

Equivariant Poincaré–Alexander–Lefschetz duality and the Cohen–Macaulay property

CHRISTOPHER ALLDAY

MATTHIAS FRANZ

VOLKER PUPPE

We prove a Poincaré–Alexander–Lefschetz duality theorem for rational torus-equivariant cohomology and rational homology manifolds. We allow non-compact and non-orientable spaces. We use this to deduce certain short exact sequences in equivariant cohomology, originally due to Duflo in the differentiable case, from similar, but more general short exact sequences in equivariant homology. A crucial role is played by the Cohen–Macaulayness of relative equivariant cohomology modules arising from the orbit filtration.

55N91; 13C14, 57R91

1 Introduction

Let $T = (S^1)^r$ be a torus, and let X be a T -space satisfying some fairly mild assumptions (see Section 2.1). Recall that $H_T^*(X) = H_T^*(X; \mathbb{Q})$, the equivariant cohomology of X with rational coefficients, can be defined as the cohomology of the Borel construction (or homotopy quotient) $X_T = (ET \times X)/T$, and that it is an algebra over the polynomial ring $R = H^*(BT)$.

In [6, page 23], A Borel observed that “even if one is interested mainly in a statement involving only cohomology, one has to use in the proof groups which play the role of homology groups, and therefore this presupposes some homology theory”. In this spirit we defined in [3] the equivariant homology $H_*^T(X)$ of X , which is a module over R . In contrast to $H_T^*(X)$, it is not the homology of any space. Nevertheless, it has many desirable properties: it is related to $H_T^*(X)$ via universal coefficient spectral sequences, and, in the case of a rational Poincaré duality space X , also through an equivariant Poincaré duality isomorphism

$$(1-1) \quad H_T^*(X) \xrightarrow{\sim} H_*^T(X), \quad \alpha \mapsto \alpha \cap o_T,$$

which is the cap product with an equivariant orientation $o_T \in H_*^T(X)$. Note that unlike the non-equivariant situation, the isomorphism (1-1) does not necessarily translate into the perfection of the equivariant Poincaré pairing

$$(1-2) \quad H_T^*(X) \times H_T^*(X) \rightarrow R, \quad (\alpha, \beta) \mapsto \langle \alpha \cup \beta, o_T \rangle.$$

In fact, the pairing (1-2) is perfect if and only if $H_T^*(X)$ is a reflexive R -module; see [3, Corollary 1.3]. Hence, in the equivariant setting Poincaré duality cannot be phrased in terms of cohomology alone. Another reason to consider equivariant homology is that sometimes it behaves better than cohomology. For example, the sequence

$$(1-3) \quad 0 \rightarrow H_*^T(X^T) \rightarrow H_*^T(X) \rightarrow H_*^T(X, X^T) \rightarrow 0$$

is always exact (see Proposition 1.1 below), which is rarely the case for the corresponding sequence in equivariant cohomology.

The first theme of the present paper is to extend Poincaré duality and its generalization Poincaré–Alexander–Lefschetz duality to the torus-equivariant setting. Equivariant Poincaré–Alexander–Lefschetz duality for compact Lie groups and certain generalized (co)homology theories has been discussed by Wirthmüller [22], Lewis and May [19, Section III.6], and May [20, Section XVI.9] in the framework of equivariant stable homotopy theory. Here we are interested in an explicit algebraic description in the context of the singular Cartan model; cf Section 2.2.

We allow rational homology manifolds that may be non-compact or non-orientable. To this end we have to define equivariant cohomology with compact supports and equivariant homology with closed supports, and, for non-orientable homology manifolds, also equivariant (co)homology with twisted coefficients.

Theorem 1.1 (Poincaré–Alexander–Lefschetz duality) *Let X be an orientable n -dimensional rational homology manifold with a T -action, and let (A, B) be a closed T -stable pair in X . Then there is an isomorphism of R -modules*

$$H_T^*(X \setminus B, X \setminus A) \cong H_{n-*}^{T,c}(A, B).$$

Here $H_*^{T,c}(A, B)$ denotes the equivariant homology of the pair (A, B) with compact supports. Theorem 1.1 extends to an isomorphism of spectral sequences induced by a T -stable filtration on X , and it implies an equivariant Thom isomorphism. We also establish analogous results for non-orientable manifolds and twisted coefficients, which is essential for our applications.

Another important result in equivariant stable homotopy theory is the Adams isomorphism. In Proposition 2.7 we prove a version of it in our context.

Our second theme is to extend the results of [3] to the new (co)homology theories and to combine them with equivariant duality results.

Recall that the equivariant i –skeleton $X_i \subset X$ is the union of all T –orbits of dimension at most i ; this defines the orbit filtration of X . A crucial observation, originally made by Atiyah [5] in the context of equivariant K –theory, is that the R –module $H_T^*(X_i, X_{i-1})$ is zero or Cohen–Macaulay of dimension $r - i$. The same holds for equivariant homology, and it implies the following result.

Proposition 1.1 *For any $0 \leq i \leq r$ there is an exact sequence*

$$0 \rightarrow H_*^T(X_i) \rightarrow H_*^T(X) \rightarrow H_*^T(X, X_i) \rightarrow 0.$$

The case $i = 0$ was made explicit in (1-3) above. Again, this extends to homology with compact supports and/or twisted coefficients; see Proposition 4.3. Using the naturality properties of equivariant Poincaré–Alexander–Lefschetz duality, we can easily generalize a result of Dufлот [14] about smooth actions on differential manifolds; see Proposition 4.11:

Corollary 1.2 *Let X be a rational homology manifold. For any $0 \leq i \leq r$ there is an exact sequence*

$$0 \rightarrow H_T^*(X, X \setminus X_i) \rightarrow H_T^*(X) \rightarrow H_T^*(X \setminus X_i) \rightarrow 0.$$

We now turn to the relation between equivariant homology and the orbit filtration. Recall that the *Atiyah–Bredon complex* $AB^*(X)$ is defined by

$$(1-4) \quad AB^i(X) = H_T^{*+i}(X_i, X_{i-1})$$

for $0 \leq i \leq r$ and zero otherwise. (We set $X_{-1} = \emptyset$.) The differential

$$(1-5) \quad d_i: H_T^*(X_i, X_{i-1}) \rightarrow H_T^{*+1}(X_{i+1}, X_i)$$

is the boundary map in the long exact sequence of the triple (X_{i+1}, X_i, X_{i-1}) . In other words, $AB^*(X)$ is the E_1 page of the spectral sequence arising from the orbit filtration and converging to $H_T^*(X)$, and $H^*(AB^*(X))$ is its E_2 page. A principal result of [3] is a natural isomorphism

$$(1-6) \quad H^i(AB^*(X)) = \text{Ext}_R^i(H_*^T(X), R)$$

for all $i \geq 0$. This is once again a consequence of the Cohen–Macaulay property of $H_*^T(X_i, X_{i-1})$. In [3] we used the isomorphism (1-6) to study syzygies in equivariant cohomology and to relate them to the Atiyah–Bredon complex. Here we again

indicate generalizations to (co)homology with the new pair of supports and/or twisted coefficients. They are used in [16] to prove a “geometric criterion” for syzygies in equivariant cohomology that only depends on the quotient X/T as a stratified space.

The paper is organized as follows. In Section 2 we first review equivariant cohomology with closed supports and equivariant homology with compact supports and then define equivariant (co)homology with the other pair of supports. We also consider homology manifolds and define variants of equivariant (co)homology with twisted coefficients in this case. Theorem 1.1 and its corollaries are proved in Section 3. Applications to the orbit structure are given in Section 4. There we also relate the cohomology of the Atiyah–Bredon complex to the question of uniformity of an action. Given the importance of (1-6), we include a direct proof of it in Section 5. It uses only exact sequences as in Proposition 1.1 and avoids the intricate reasoning with spectral sequences done in [3].

Acknowledgements

We thank the referee for numerous helpful comments and in particular for suggesting Proposition 2.7, a stronger version of one of our earlier results. MF was partially supported by an NSERC Discovery Grant.

2 Equivariant homology and cohomology

2.1 Notation and standing assumptions

We write “ \subset ” for inclusion of sets and “ \subsetneq ” for proper inclusion.

Throughout this paper, $T = (S^1)^r$ denotes a compact torus of rank $r \geq 0$, and \mathbb{k} a field. From Section 4 on we will assume that the characteristic of \mathbb{k} is zero. All (co)homology is taken with coefficients in \mathbb{k} unless specified otherwise.

$C_*(-)$ and $C^*(-)$ denote normalized singular chains and cochains with coefficients in the field \mathbb{k} , and $H_*(-)$ and $H^*(-)$ singular (co)homology. We adopt a cohomological grading, so that the homology of a space lies in non-positive degrees; an element $c \in H_i(X)$ has cohomological degree $-i$.

$R = H^*(BT)$ is the symmetric algebra generated by $H^2(BT)$, and $\mathfrak{m} \triangleleft R$ its maximal homogeneous ideal. All R -modules are assumed to be graded. We consider \mathbb{k} as an R -module (concentrated in degree 0) via the canonical augmentation. For an R -module M and an $l \in \mathbb{Z}$ the notation $M[l]$ denotes a degree shift by l , so that the degree i piece of $M[l]$ is the degree $i - l$ piece of M . For the cohomology of

some space, we alternatively write $H^*(X)[l]$ or $H^{*-l}(X)$. Due to the cohomological grading, we have in homology the identity $H_*(X)[l] = H_{*+l}(X)$.

We assume all spaces to be Hausdorff, second-countable, locally compact, locally contractible and of finite covering dimension, hence also completely regular, separable and metrizable. Important examples are topological (in particular, smooth) manifolds, orbifolds, complex algebraic varieties, and countable, locally finite CW complexes. We also assume that only finitely many distinct isotropy groups occur in any T -space X .

Remark 2.1 Under these assumptions on a T -space X , the orbit space X/T is again Hausdorff and locally compact (Bredon [8, Theorem 3.1]), second-countable, locally contractible (Conner [12, Theorem 3.8, Corollary 3.12]) and of finite covering dimension (Borel [6, Theorem VIII.3.16]). It is easy to see that the same applies to the fixed point set X^T with the exception of local contractibility: see Remark 2.17 below.

It follows from our assumptions that every subset $A \subset X$ is paracompact, hence singular cohomology and Alexander–Spanier cohomology are naturally isomorphic for all pairs (A, B) such that A and B are locally contractible. We therefore put as another standing assumption that all subsets $A \subset X$ we consider are locally contractible; this holds automatically if A is open in X . And we call (A, B) a T -pair if A and B are T -stable.

In addition we will put a finiteness condition on the (co)homology of the spaces and pairs we consider. This will be explained in detail once we have defined equivariant (co)homology.

2.2 The singular Cartan model

Let X be a T -space. We recall from [3, Section 3] the definition of equivariant homology and cohomology via the “singular Cartan model”. As pointed out in [3], it can be replaced by the usual Cartan model for differentiable actions on manifolds and $\mathbb{k} = \mathbb{R}$.

The *singular Cartan model* of the T -pair (A, B) in X is

$$(2-1) \quad C_T^*(A, B) = C^*(A, B) \otimes R$$

with R -linear differential

$$(2-2) \quad d(\gamma \otimes f) = d\gamma \otimes f + \sum_{i=1}^r a_i \cdot \gamma \otimes t_i f$$

and R -bilinear product

$$(2-3) \quad (\gamma \otimes f) \cup (\gamma' \otimes f') = \gamma \cup \gamma' \otimes ff'.$$

Here t_1, \dots, t_r are a basis of $H^2(BT) \subset R$, and a_1, \dots, a_r are representative loops of the dual basis of $H_1(T)$; the product $a_i \cdot \gamma$ refers to the action of $C_*(T)$ on $C^*(X)$ induced by the T -action on X . The equivariant chain complex $C_*^T(A, B)$ is the R -dual of (2-1),

$$(2-4) \quad C_*^T(A, B) = \text{Hom}_R(C_T^*(A, B), R).$$

Equivariant cohomology and homology are defined as

$$(2-5) \quad H_T^*(A, B) = H^*(C_T^*(A, B)),$$

$$(2-6) \quad H_*^T(A, B) = H_*(C_*^T(A, B)).$$

This definition of $H_T^*(A, B)$ is naturally isomorphic, as an R -algebra, to the usual one based on the Borel construction X_T .

2.3 Other supports

Let (A, B) be a closed T -pair in a T -space X . We define the *equivariant cohomology of (A, B) with compact supports* by

$$(2-7) \quad H_{T,c}^*(A, B) = \varinjlim H_T^*(U, V) = H^*(C_{T,c}^*(A, B)),$$

where

$$(2-8) \quad C_{T,c}^*(A, B) = \varinjlim C_T^*(U, V) = \left(\varinjlim C^*(U, V) \right) \otimes R,$$

and the direct limits are taken over all T -stable open neighbourhood pairs (U, V) of (A, B) such that $X \setminus V$ is compact. By tautness and excision, $H_{T,c}^*(A, B)$ is easily seen to be naturally isomorphic to the Alexander–Spanier cohomology of the closure of (A, B) in the one-point compactification of X relative to the added point. Hence it does not matter whether (A, B) is considered as a closed T -pair in X or in A .

The *equivariant homology of (A, B) with closed supports* is defined by taking the R -dual of (2-8),

$$(2-9) \quad C_*^{T,c}(A, B) = \text{Hom}_R(C_{T,c}^*(A, B), R),$$

$$(2-10) \quad H_*^{T,c}(A, B) = H_*(C_*^{T,c}(A, B)).$$

Clearly, we have $H_{T,c}^*(A, B) = H_T^*(A, B)$ and $H_*^{T,c}(A, B) = H_*^T(A, B)$ if X is compact.

2.4 Properties

We list several important properties of equivariant (co)homology, omitting proofs that were given in [3]. In Section 2.6 we will extend all results of this section to homology manifolds and (co)homology with twisted coefficients; see Remark 2.15.

Assumption 2.2 For the rest of this paper we assume that $H^*(A, B)$ is a finite-dimensional \mathbb{k} -vector space for any T -pair (A, B) for which we consider equivariant cohomology with closed supports or equivariant homology with compact supports. By Proposition 2.3 below, this implies that both $H_T^*(A, B)$ and $H_*^T(A, B)$ are finitely generated R -modules. (Each of the latter conditions is actually equivalent to the former.)

Proposition 2.3 (Serre spectral sequence) *Let (A, B) be a T -pair in X . There are spectral sequences, natural in (A, B) , with*

$$\begin{aligned} E_1 = E_2 = H^*(A, B) \otimes R &\Rightarrow H_T^*(A, B), \\ E_1 = E_2 = H_*(A, B) \otimes R &\Rightarrow H_*^T(A, B). \end{aligned}$$

Proof These are equations (3.5) and (3.7) in [3]. □

Proposition 2.4 (Universal coefficient theorem [3, Proposition 3.5]) *Let (A, B) be a T -pair in X . There are spectral sequences, natural in (A, B) , with*

$$\begin{aligned} E_2^p = \text{Ext}_R^p(H_T^*(A, B), R) &\Rightarrow H_*^T(A, B), \\ E_2^p = \text{Ext}_R^p(H_*^T(A, B), R) &\Rightarrow H_T^*(A, B). \end{aligned}$$

For a multiplicative subset $S \subset R$ and a T -space X , define the T -stable subset

$$(2-11) \quad X^S = \{x \in X \mid S \cap \ker(H^*(BT) \rightarrow H^*(BT_x)) = \emptyset\} \subset X.$$

It is closed in X , cf [4, page 132]. For example, $X^S = X^T$ if $\text{char } \mathbb{k} = 0$ and S contains all non-zero linear polynomials.

Proposition 2.5 (Localization theorem) *Let (A, B) be a T -pair in X , and let $S \subset R$ be a multiplicative subset. Then the inclusion $X^S \hookrightarrow X$ induces isomorphisms of $S^{-1}R$ -modules*

$$\begin{aligned} S^{-1}H_T^*(A, B) &\rightarrow S^{-1}H_T^*(A^S, B^S), \\ S^{-1}H_*^T(A, B) &\rightarrow S^{-1}H_*^T(A, B). \end{aligned}$$

Proof The localization theorem for equivariant cohomology with closed supports is classical; cf [4, Chapter 3]. (Recall that only finitely many orbit types occur in X .)

By the universal coefficient theorem, there is a spectral sequence converging to $H_*^T(A, B)$ with E_2 page $\text{Ext}_R(H_T^*(A, B), R)$, and similarly for the pair (A^S, B^S) . The inclusion $X^S \hookrightarrow X$ gives rise to a map of spectral sequences, which on the E_2 pages is the canonical map

$$(2-12) \quad \text{Ext}_R(H_T^*(A^S, B^S), R) \rightarrow \text{Ext}_R(H_T^*(A, B), R).$$

Since localization is an exact functor, the S -localization of (2-12) is the map

$$(2-13) \quad \text{Ext}_{S^{-1}R}(S^{-1}H_T^*(A^S, B^S), S^{-1}R) \rightarrow \text{Ext}_{S^{-1}R}(S^{-1}H_T^*(A, B), S^{-1}R),$$

which is an isomorphism by the cohomological localization theorem. Hence, the localization of $H_*^T(A^S, B^S) \rightarrow H_*^T(A, B)$ is an isomorphism as well. \square

Let $K \subset T$ be a subtorus, say of rank p , with quotient $L = T/K$. In this case we have canonical morphisms of algebras

$$(2-14) \quad H^*(BL) = R_L = \mathbb{k}[t_{p+1}, \dots, t_r] \rightarrow R \rightarrow H^*(BK) = R_K = \mathbb{k}[t_1, \dots, t_p].$$

Moreover, any choice of splitting $T \cong K \times L$ defines an isomorphism $R = R_K \otimes R_L$.

Proposition 2.6 *Let $K \subset T$ be a subtorus with quotient $L = T/K$. Let (A, B) be a closed T -pair in X such that K acts trivially on $A \setminus B$. Then there are isomorphisms of R -modules*

$$\begin{aligned} H_T^*(A, B) &= H_L^*(A, B) \otimes_{R_L} R, \\ H_*^T(A, B) &= H_*^L(A, B) \otimes_{R_L} R. \end{aligned}$$

The result holds for any T -pair (A, B) if K acts trivially on all of A .

In the proof below as well as in that of Proposition 2.7 we will use the following fact; cf [4, Corollary B.1.13]: Let $\phi: M \rightarrow N$ be a quasi-isomorphism of dg R -modules. If M and N are free as R -modules, then ϕ is a homotopy equivalence over R .

Proof Since B is closed in A , we have, by tautness and excision, a quasi-isomorphism of dg R -modules

$$(2-15) \quad C_T^*(A, B) \rightarrow \varinjlim C_T^*(A \setminus B, U \setminus B) = (\varinjlim C^*(A \setminus B, U \setminus B)) \otimes R,$$

where the direct limit is taken over all T -stable open sets $U \supset B$. Hence we may work with this direct limit, which we denote by M .

Now choose a splitting $T = K \times L$. By [3, Proposition 3.4], we may assume that the representatives $a_i \in C_1(T)$ appearing in the “Cartan differential” (2-2) are chosen such that $a_1, \dots, a_p \in C_1(K)$ and $a_{p+1}, \dots, a_r \in C_1(L)$. Since we are using normalized singular (co)chains, $C_*(K)$ acts trivially on each $C^*(A \setminus B, U \setminus B)$. The differential on M therefore takes the form

$$(2-16) \quad d(\gamma \otimes f) = d\gamma \otimes f + \sum_{i=p+1}^r a_i \cdot \gamma \otimes t_i f,$$

which implies

$$(2-17) \quad H_T^*(A, B) = H_L^*(A, B) \otimes H^*(BK) = H_L^*(A, B) \otimes_{R_L} R$$

by the Künneth formula.

By the remark made above, the quasi-isomorphism (2-15) is a homotopy equivalence, which is preserved by the functor $\text{Hom}_R(-, R)$. For equivariant homology we can therefore argue analogously.

The last claim follows, by the five-lemma, from the previous one, applied to A and B separately, and the long exact sequence of the pair. □

At the other extreme, we have the following:

Proposition 2.7 *Let $K \subset T$ be a subtorus, say of rank p , with quotient $L = T/K$. Let (A, B) be closed a T -pair in X such that K acts freely on $A \setminus B$ (or just locally freely in case $\text{char } \mathbb{k} = 0$). Then $H^*(A/K, B/K)$ is finite-dimensional, and there are isomorphisms of R_L -modules*

$$\begin{aligned} H_T^*(A, B) &= H_L^*(A/K, B/K), \\ H_*^T(A, B) &= H_{*-p}^L(A/K, B/K). \end{aligned}$$

The result holds for any T -pair (A, B) if K acts (locally) freely on all of A .

The cohomological part is well-known; cf [4, Proposition 3.10.9]. That a degree shift by $-p$ is necessary for the homological part can already be seen by considering $K = T = X$: In this case one has $H_*^T(X) = \mathbb{k}[-r] = H_{*-r}(X/T)$; cf [3, Example 3.6].

Geometrically, the homological isomorphism can be understood as a transfer for the quotient map $X \rightarrow X/K$. Since, in the singular setting, it is delicate to define a transfer map or integration over the fibre on the (co)chain level, we will follow an algebraic approach and postpone the geometrical aspects to our discussion of Poincaré–Alexander–Lefschetz duality (Remark 3.10). The homology isomorphism can also be

viewed as a version of the Adams isomorphism in equivariant stable homotopy theory (see [19, Section II.7; 20, Section XVI.5]) in our algebraic context.

The proof of Proposition 2.7 requires some preparation. Recall that $\mathfrak{m} = (t_1, \dots, t_r)$ is the maximal graded ideal in R . In the proof below we will use the local duality isomorphism

$$(2-18) \quad H_{\mathfrak{m}}^j(M) = \text{Ext}_R^{r-j}(M, R[2r])^\vee,$$

which is natural in the R -module M ; see for instance Eisenbud [15, Theorem A1.9] (where the generators of the polynomial ring are assigned the degree 1, not 2). The symbol “ \vee ” in (2-18) denotes the dual of a graded \mathbb{k} -vector space. We will also need the Čech complex computing $H_{\mathfrak{m}}^*(M)$ by means of some generators of \mathfrak{m} as in [15, p. 189].

More generally, we consider the Čech complex for a dg R -module M . Thus we obtain a bicomplex $C_{\mathfrak{m}}^{*,*}(M)$ with first differential d^I coming from M and second differential d^{II} coming from the Čech complex for the canonical generators t_1, \dots, t_r . An element in $C_{\mathfrak{m}}^{i,j}(M)$ is a sum of elements of degree j in the i -fold localizations in this Čech complex. While j is unbounded in both directions, we have $0 \leq i \leq r$, so that both filtrations of the bicomplex are regular (Bredon [11, page 452]). Hence both associated spectral sequences converge to $H_{\mathfrak{m}}^*(M)$, the cohomology of $C_{\mathfrak{m}}^{*,*}(M)$ with respect to the total differential.

In the first bicomplex spectral sequence we have

$$(2-19) \quad {}^I E_1 = C_{\mathfrak{m}}^{*,*}(H^*(M)),$$

$$(2-20) \quad {}^I E_2 = H_{\mathfrak{m}}^*(H^*(M)),$$

since the cohomology of the localization of M is the localization of the cohomology.

Taking the other bicomplex spectral sequence, we get

$$(2-21) \quad {}^{II} E_1 = {}^{II} H_{\mathfrak{m}}^*(M)$$

where ${}^{II} H_{\mathfrak{m}}^*(M)$ means the cohomology of $C_{\mathfrak{m}}^{*,*}(M)$ with respect to the differential d^{II} , that is, the local cohomology of the R -module M with trivial differential.

Suppose that M is finitely generated and free as an R -module. By local duality one then has that the E_1 page

$$(2-22) \quad {}^{II} E_1^k = {}^{II} H_{\mathfrak{m}}^k(M) = \begin{cases} \text{Hom}_R(M, R[2r])^\vee & \text{if } k = r, \\ 0 & \text{otherwise,} \end{cases}$$

is concentrated in the column $k = r$, and therefore

$$(2-23) \quad H_m^*(M) = H^*(\text{Hom}_R(M, R[2r]))^\vee[r] = H^*(\text{Hom}_R(M, R))^\vee[-r].$$

If M is R –homotopy equivalent to some M' , then so are $C_m^{*,*}(M)$ and $C_m^{*,*}(M')$, hence $H_m^*(M) \cong H_m^*(M')$ as R –modules. In particular, if $M = C_T^*(X)$, then it is R –homotopy equivalent to a dg R –module M' that is finitely generated and free as an R –module. We therefore conclude that

$$(2-24) \quad H_m^*(C_T^*(X)) = H^*(\text{Hom}_R(C_T^*(X), R))^\vee[-r]$$

$$(2-25) \quad = H^*(C_*^T(X))^\vee[-r] = H_*^T(X)^\vee[-r].$$

Let $\mathfrak{m}_L = (t_{p+1}, \dots, t_r)$ be the maximal graded ideal of R_L . Using the canonical generators, we can similarly define $C_{\mathfrak{m}_L}^{*,*}(-)$ and $H_{\mathfrak{m}_L}^*(-)$ for dg R_L –modules, hence a fortiori for dg R –modules. Since these generators are among the chosen generators of \mathfrak{m} , we have a canonical map of bicomplexes

$$(2-26) \quad C_m^{*,*}(M) \rightarrow C_{\mathfrak{m}_L}^{*,*}(M)$$

for any dg R –module M , inducing a map of R –modules $H_m^*(M) \rightarrow H_{\mathfrak{m}_L}^*(M)$.

Lemma 2.8 *Let (A, B) be a closed T –pair in X . Assume that K acts freely on $A \setminus B$, and that all $x \in A \setminus B$ have the same isotropy group, say K' . Then the map $H_m^*(H_T^*(A, B)) \rightarrow H_{\mathfrak{m}_L}^*(H_T^*(A, B))$ is an isomorphism.*

If $\text{char } \mathbb{k} = 0$, then it is enough that K acts locally freely and that the isotropy groups in $A \setminus B$ have the same identity component K' .

Proof Since K acts (locally) freely, the composition $K' \rightarrow T \rightarrow L$ is injective (or has finite kernel). This implies that the composition $H^*(BL) \rightarrow H^*(BT) \rightarrow H^*(BK')$ is surjective. Hence there are $t'_1, \dots, t'_p \in \mathfrak{m}_L$ such that t_i and t'_i map to the same element in $H^*(BK')$ for $1 \leq i \leq p$, and $u_i = t_i - t'_i$ maps to 0. By the localization theorem (Proposition 2.5), this implies that the localization of $H_T^*(A, B)$ at u_i vanishes.

We observe that $u_1, \dots, u_p, t_{p+1}, \dots, t_r$ also generate \mathfrak{m} . Since local cohomology can be computed from any set of generators (cf [15, Theorem A1.3]), we can assume that one has chosen these generators instead of the canonical generators t_1, \dots, t_r . Then the terms in the Čech complex involving at least one of the u_i drop out, and we are left with the Čech complex computing $H_{\mathfrak{m}_L}^*(H_T^*(A, B))$. □

Proof of Proposition 2.7 We choose a splitting $T = K \times L$ with compatibly chosen representatives $a_i \in C_1(T)$ as in the proof of Proposition 2.6.

As mentioned already, the isomorphism

$$(2-27) \quad H_T^*(A, B) = H_L^*(A/K, B/K)$$

is classical (and requires that B is closed in A). It is induced by the quasi-isomorphism of dg R_L -modules

$$(2-28) \quad C_L^*(A/K, B/K) = C^*(A/K, B/K) \otimes R_L \rightarrow C_T^*(A, B) = C^*(A, B) \otimes R, \\ \gamma \otimes f \mapsto \pi^* \gamma \otimes f,$$

where $\pi: X \rightarrow X/K$ is the projection.

It follows from the localization theorem that the localization of $H_K^*(A, B)$ at each generator t_i of R_K vanishes. Since $H_K^*(A, B)$ is finitely generated over R_K by Assumption 2.2, this implies that $H_K^*(A, B)$ is killed by some power of each t_i and therefore that it is finite-dimensional as \mathbb{k} -vector space. By taking $T = K$ in (2-27), we see that $H^*(A/K, B/K)$ is also finite-dimensional.

For the homological statement we start by proving that the canonical map

$$(2-29) \quad C_m^{*,*}(C_T^*(A, B)) \rightarrow C_{m_L}^{*,*}(C_T^*(A, B))$$

is a quasi-isomorphism. We proceed by induction on the number m of (connected) orbit types in $A \setminus B$. For $m = 0$ there is nothing to show as $A = B$ in this case. Otherwise fix an orbit type of maximal dimension in $A \setminus B$ and let $A' \subset A$ be the union of B and all other orbit types; A' is T -stable and closed in A .

The short exact sequence

$$(2-30) \quad 0 \rightarrow C_T^*(A, A') \rightarrow C_T^*(A, B) \rightarrow C_T^*(A', B) \rightarrow 0$$

gives rise to the commutative diagram

$$(2-31) \quad \begin{array}{ccccccc} 0 & \longrightarrow & C_m^{*,*}(C_T^*(A, A')) & \longrightarrow & C_m^{*,*}(C_T^*(A, B)) & \longrightarrow & C_m^{*,*}(C_T^*(A', B)) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & C_{m_L}^{*,*}(C_T^*(A, A')) & \longrightarrow & C_{m_L}^{*,*}(C_T^*(A, B)) & \longrightarrow & C_{m_L}^{*,*}(C_T^*(A', B)) \longrightarrow 0 \end{array}$$

whose horizontal sequences are again short exact. The right vertical arrow is a quasi-isomorphism by induction. To see that the left one is so as well, we consider the induced map between the E_2 pages of the first bicomplex spectral sequences (2-20). In our case this is the map

$$(2-32) \quad H_m^*(H_T^*(A, A')) \rightarrow H_{m_L}^*(H_T^*(A, A')),$$

and it is an isomorphism by Lemma 2.8 and our choice of A' . The map induced in cohomology by the left arrow above therefore is also an isomorphism. Hence the middle arrow is a quasi-isomorphism by the five-lemma, which proves the claim.

The quasi-isomorphism (2-28) is in fact a homotopy equivalence over R_L as both sides are free as R_L -modules. We therefore get isomorphisms of R_L -modules

$$(2-33) \quad H_*^T(A, B)^\vee[-r] = H_m^*(C_T^*(A, B)) = H_{m_L}^*(C_T^*(A, B))$$

$$(2-34) \quad = H_{m_L}^*(C_L^*(A/K, B/K)) = H_*^L(A/K, B/K)^\vee[-(r-p)],$$

which translates into the claimed isomorphism

$$(2-35) \quad H_*^T(A, B) \rightarrow H_*^L(A/K, B/K)[-p] = H_{*-p}^L(A/K, B/K).$$

The last claim follows again from the absolute case and the five-lemma. □

All these results hold as well for cohomology with compact supports and homology with closed supports and closed T -pairs (A, B) , assuming that $H_c^*(A, B)$ is a finite-dimensional \mathbb{k} -vector space; cf Assumption 2.2. The proofs are identical; the localization theorem for cohomology with compact supports follows from the version for closed supports since direct limits preserve isomorphisms.

Proposition 2.9 *For any closed T -pair (A, B) in X there are isomorphisms of R -modules*

$$H_{T,c}^*(A, B) = H_{T,c}^*(A \setminus B),$$

$$H_*^{T,c}(A, B) = H_*^{T,c}(A \setminus B).$$

Proof The first identity follows from excision and the fact that a direct limit is an exact functor. The second identity then is a consequence of the universal coefficient theorem. □

2.5 Homology manifolds

Let X be a \mathbb{k} -homology manifold, say of dimension n . By this we mean a connected space X such that for any $x \in X$ one has

$$(2-36) \quad H_i(X, X \setminus \{x\}) \cong \begin{cases} \mathbb{k} & \text{if } i = n, \\ 0 & \text{if } i \neq n. \end{cases}$$

If in addition $H_n^c(X) \cong \mathbb{k}$, then X is called *orientable*. Homology manifolds are an appropriate setting for Poincaré duality; see Lemma 3.1 below.

Assumption 2.10 We assume that any homology manifold X we consider is orientable or admits an orientable two-fold covering $\pi: \tilde{X} \rightarrow X$.

For non-orientable X , such a covering will be called an *orientation cover*. Note that \tilde{X} is necessarily connected. For orientable X we define the trivial two-fold covering to be the orientation cover. We will use orientation covers to define (co)homology with twisted coefficients in Section 2.6.

Remark 2.11 Any \mathbb{Z} -homology manifold admits an orientation cover, but it seems unclear whether this holds for arbitrary \mathbb{k} -homology manifolds; see the discussion in [11, page 331]. On the other hand, if an orientation cover exists, then it is unique. For orientable X , this is true by definition. For non-orientable X it can be seen as follows:

Let γ be a loop at $x \in X$. By transporting local orientations along γ , we get an automorphism of $H_n(X, X \setminus \{x\})$ (cf [7, page 39]), which is necessarily multiplication by some non-zero scalar. This induces a morphism $\phi: \pi_1(X) \rightarrow \mathbb{k}^\times$. The connected orientable covers of X are of the form \tilde{X}/G where \tilde{X} is the universal cover and G a subgroup of the kernel of ϕ . In particular, there is at most one orientation cover.

The following observation seems to be well-known, but we could not find a suitable reference.

Lemma 2.12 *Assume $\text{char } \mathbb{k} = 0$. Any connected, locally orientable orbifold is a \mathbb{k} -homology manifold satisfying Assumption 2.10.*

See Adem, Leida and Ruan [1, Section 1.1] or Satake [21] for the definition of an orbifold. By “locally orientable” we mean that locally the orbifold X , say of dimension n , is the quotient of an open ball in \mathbb{R}^n by a finite subgroup of $\text{SO}(n)$.

Proof Condition (2-36) holds because one locally divides by a finite subgroup of $\text{SO}(n)$ and $\text{char } \mathbb{k} = 0$.

The existence of an orientation cover can be shown in the same way as for manifolds. Recall that in the smooth case one proceeds as follows (cf Lee [18, Chapter 15–17]): If X admits an oriented atlas, that is, if the charts of X can be oriented in a way consistent with coordinate changes, then one can integrate differential forms with compact supports, and the integration map provides an isomorphism $H_n^c(X) \cong \mathbb{k}$. Otherwise $H_n^c(X) = 0$, and one can construct a connected double cover with oriented atlas by doubling all charts and gluing them according to whether coordinate changes preserve or reverse chart orientations. Hence X is orientable in our sense if and only if it admits an oriented atlas.

For an orbifold X one can also define differential forms with compact supports, and if X is locally orientable and has an atlas of compatibly oriented charts, then one can integrate these forms; cf [21, Section 8]. If such an atlas does not exist, then one can again pass to an oriented two-fold cover. Now the proofs for manifolds go through without change. \square

Lemma 2.13 *Let X be a \mathbb{k} –homology manifold with orientation cover $\pi: \tilde{X} \rightarrow X$. Any T –action on X lifts to a T –action on \tilde{X} .*

See [8, Corollary I.9.4] for an analogous result in the context of topological manifolds.

Proof The case of orientable X is trivial. If X is non-orientable, then by [8, Section I.9] the T –action on X lifts to a \tilde{T} –action on \tilde{X} , where \tilde{T} is a two-fold covering of T and $\ker(\tilde{T} \rightarrow T) \cong \mathbb{Z}_2$ acts by deck transformations. If the non-trivial deck transformation τ were orientation-preserving, then X would have to be orientable because $H_n^c(X) = H_n^c(\tilde{X})^\tau \cong \mathbb{k}$, where $n = \dim X$. So τ does not preserve orientations, which implies that \tilde{T} cannot be connected. Hence its identity component is T , and the action lifts. \square

2.6 Twisted coefficients

The aim of this section is to introduce equivariant (co)homology with twisted coefficients $\tilde{\mathbb{k}}$. To distinguish it from the (co)homology we have considered so far, the latter will be called (co)homology with constant coefficients \mathbb{k} from now on. Twisted coefficients are only interesting if the characteristic of the ground field \mathbb{k} differs from 2, which we assume in this section. For $\text{char } \mathbb{k} = 2$, (co)homology with twisted coefficients is defined to be the same as (co)homology with constant coefficients.

We focus on cohomology with closed supports and homology with compact supports. All results are equally valid for the other pair of supports; we will indicate when proofs for that case need additional arguments.

Let X be a \mathbb{k} –homology manifold (which, by our definition, is connected) with orientation cover $\pi: \tilde{X} \rightarrow X$ and non-trivial deck transformation τ . For a pair (A, B) in X , we write $(\tilde{A}, \tilde{B}) = (\pi^{-1}(A), \pi^{-1}(B))$. Moreover, we denote the involution of $C^*(\tilde{A}, \tilde{B})$ induced by τ by the same letter. Since $2 \in \mathbb{k}$ is invertible, we get a decomposition

$$(2-37) \quad C^*(\tilde{A}, \tilde{B}) = C^*(\tilde{A}, \tilde{B})_+ \oplus C^*(\tilde{A}, \tilde{B})_-$$

into the eigenspaces of τ for the eigenvalues ± 1 . Note that π^* is an isomorphism of $C^*(A, B)$ onto $C^*(\tilde{A}, \tilde{B})_+$. We define $C^*(A, B; \mathbb{k})$, the cochains on (A, B) with

twisted coefficients, to be the eigenspace for the eigenvalue -1 of τ . Hence the splitting (2-37) becomes

$$(2-38) \quad C^*(\tilde{A}, \tilde{B}) = C^*(A, B) \oplus C^*(A, B; \tilde{\mathbb{k}})$$

and induces an analogous decomposition in cohomology,

$$(2-39) \quad H^*(\tilde{A}, \tilde{B}) = H^*(A, B) \oplus H^*(A, B; \tilde{\mathbb{k}}).$$

We now assume that X is equipped with a T -action and that the pair (A, B) is T -stable. Since the decomposition (2-38) is $C_*(T)$ -stable, we can define *equivariant (co)homology with twisted coefficients* in a way analogous to Section 2.2:

$$(2-40) \quad C_T^*(A, B; \tilde{\mathbb{k}}) = C_T^*(\tilde{A}, \tilde{B})_- = C^*(A, B; \tilde{\mathbb{k}}) \otimes R$$

with the same differential as in (2-2),

$$(2-41) \quad H_T^*(A, B; \tilde{\mathbb{k}}) = H^*(C_T^*(A, B; \tilde{\mathbb{k}})),$$

$$(2-42) \quad C_*^T(A, B; \tilde{\mathbb{k}}) = \text{Hom}_R(C_T^*(A, B; \tilde{\mathbb{k}}), R),$$

$$(2-43) \quad H_*^T(A, B; \tilde{\mathbb{k}}) = H_*(C_*^T(A, B; \tilde{\mathbb{k}})).$$

Note that one has decompositions

$$(2-44) \quad H_T^*(\tilde{A}, \tilde{B}) = H_T^*(A, B) \oplus H_T^*(A, B; \tilde{\mathbb{k}}),$$

$$(2-45) \quad H_*^T(\tilde{A}, \tilde{B}) = H_*^T(A, B) \oplus H_*^T(A, B; \tilde{\mathbb{k}}).$$

(For $H_{T,c}^*(-)$ and $H_*^{T,c}(-)$ they follow from the fact that sets of the form \tilde{V} such that the complement of $V \subset X$ is compact are cofinal among all subsets of \tilde{X} with compact complement.) Of course, one already has decompositions on the (co)chain level.

Assumption 2.2 is extended as follows:

Assumption 2.14 For any T -pair (A, B) in a \mathbb{k} -homology manifold X and any (co)homology theory we are going to consider, we assume that the non-equivariant cohomology of the cover (\tilde{A}, \tilde{B}) is finite-dimensional over \mathbb{k} . In light of (2-39), this is equivalent to both the cohomology with constant coefficients and that with twisted coefficients being finite-dimensional. By Proposition 2.3, this in turn implies that the equivariant (co)homology of (A, B) with constant or twisted coefficients is finitely generated over R .

Our definition of $H^*(A, B; \tilde{\mathbb{k}})$ does not require A or B to be \mathbb{k} -homology manifolds themselves. But if A is connected and open in X , then it is a \mathbb{k} -homology manifold as

well, and the restriction of π to A is the orientation cover of A . Hence the definition of twisted coefficients is independent of the ambient space in this case.

Remark 2.15 All results from Section 2.4 (Serre spectral sequences, universal coefficient theorems and localization theorems) carry over to twisted coefficients. To see this, one can either redo the proofs with twisted (co)homology, or one can reduce the new results to the untwisted case by using the splittings (2-44) and (2-45).

Remark 2.16 An alternative way to define cohomology with twisted coefficients is to use local coefficient systems. This could be done as well in the equivariant setting, and one could even dispense with Assumption 2.10. The drawback of this approach would be that one cannot reduce statements to the case of constant coefficients anymore. In particular, one would need to prove a generalization of Proposition 2.7 (essentially, of the Vietoris–Begle mapping theorem) to local coefficients, which is required to prove Proposition 4.1.

Remark 2.17 We are mainly interested in applying our results to the fixed point sets X^K of subtori $K \subset T$, and because we want to use the localization theorem for singular cohomology (Proposition 2.5), we put local contractability into the standing assumptions in Section 2.1

Now it is a small step from (2-8) to using Alexander–Spanier cohomology for all closed invariant pairs (A, B) , cf [3, Remark 4.7]. Thus it is not, in fact, necessary to assume closed subsets to be locally contractible since the localization theorem for Alexander–Spanier cohomology does not need this assumption. We would, however, continue to assume that the ambient space X satisfies the standing assumptions; and we do not know of any torus action on such a space where the fixed point sets are not locally contractible, but nor do we know a proof that they always are.

3 Equivariant duality results

3.1 Poincaré duality

Let \mathbb{k} be a field. We start with the statement of non-equivariant Poincaré duality for orientable homology manifolds in our setting because it is not easy to locate it in the literature in the desired generality.

Lemma 3.1 *Let X be an orientable \mathbb{k} -homology manifold of dimension n . For any non-zero $o \in H_n^c(X)$, the cap product map*

$$H_c^*(X) \rightarrow H_{n-*}(X), \quad \alpha \mapsto \alpha \cap o$$

is an isomorphism.

Such an o is called an orientation of X ; it generalizes the notion of a fundamental class of a manifold.

Proof Recall that X is assumed to be a locally compact and locally contractible second-countable Hausdorff space. Sheaf (co)homology and singular (co)homology (with closed or compact supports) are therefore naturally isomorphic on X ; cf [11, Theorem III.1.1, Corollary V.12.17, Corollary V.12.21].

As mentioned in the proof of [11, Corollary V.16.9], the stalks of the orientation sheaf on X are given by (2-36). Hence X is an n -dimensional homology manifold over \mathbb{k} in the sense of [11, Definition V.9.1]. Moreover, by [11, Theorem V.16.16(f)] our definition of orientability coincides with the one in [11, Definition V.9.1]. By [11, Theorem V.9.2, Corollary V.10.2], the sheaf-theoretically defined cap product with o is an isomorphism. This map coincides with the cap product in the singular theory given above; cf [11, Example V.22]. □

Now let X be a T -space and a not necessarily orientable \mathbb{k} -homology manifold of dimension n with orientation cover \tilde{X} . The cup product in \tilde{X} is τ -equivariant, so that we obtain a pairing

$$(3-1) \quad C_{T,c}^*(X; \tilde{\mathbb{k}}) \otimes C_T^*(X) \rightarrow C_{T,c}^*(X; \tilde{\mathbb{k}}),$$

hence a cap product

$$(3-2) \quad H_{T,c}^*(X; \tilde{\mathbb{k}}) \otimes H_*^{T,c}(X; \tilde{\mathbb{k}}) \rightarrow H_*^T(X), \quad \alpha \otimes b \mapsto \alpha \cap b.$$

Extending the above definition, an *orientation* of X is a non-zero element $o \in H_n^c(X; \tilde{\mathbb{k}}) \subset H_n^c(\tilde{X})$. An *equivariant orientation* is an element $o_T \in H_n^{T,c}(X; \tilde{\mathbb{k}})$ that restricts to an orientation under the restriction map $H_*^{T,c}(X; \tilde{\mathbb{k}}) \rightarrow H_*^c(X; \tilde{\mathbb{k}})$.

Proposition 3.2 *Let X be an n -dimensional \mathbb{k} -homology manifold. Any orientation o of X lifts uniquely to an equivariant orientation o_T . Moreover, taking the cap product with o_T gives an isomorphism of R -modules*

$$H_{T,c}^*(X; \tilde{\mathbb{k}}) \xrightarrow{\cap o_T} H_{n-*}^T(X)$$

and, dually, an isomorphism

$$H_*^{T,c}(X; \tilde{\mathbb{k}}) \longrightarrow H_T^{n-*}(X).$$

Proof The canonical projection $H_*^c(X; \tilde{\mathbb{k}}) \otimes R \rightarrow H_*^c(X; \tilde{\mathbb{k}})$ is the edge homomorphism of the E_2 page of the Serre spectral sequence for $H_*^{T,c}(X; \tilde{\mathbb{k}})$ (Proposition 2.3 and Remark 2.15). Since $H_*^c(X) \otimes R$ lives in homological degrees at most n , there

are no higher differentials, and the map $H_n^{T,c}(X; \tilde{\mathbb{k}}) \rightarrow H_n^c(X; \tilde{\mathbb{k}})$ is an isomorphism. Hence any orientation lifts uniquely to an equivariant orientation.

To prove the first isomorphism, let us assume for the moment that X is orientable. Applying the Serre spectral sequence to the map

$$(3-3) \quad H_{T,c}^*(X) \rightarrow H_*^T(X), \quad \alpha \mapsto \alpha \cap o_T,$$

we find on the E_2 level the R –linear extension

$$(3-4) \quad H_c^*(X) \otimes R \rightarrow H_*(X) \otimes R, \quad \alpha \otimes f \mapsto \alpha \cap o \otimes f$$

of the non-equivariant Poincaré duality isomorphism from Lemma 3.1, which is therefore an isomorphism, too. The non-orientable case reduces to the orientable one: Since $H_n^c(\tilde{X}) = H_n^c(\tilde{X})_- = H_n^c(X; \tilde{\mathbb{k}})$, capping with $o_T = \tilde{o}_T$ restricts to the claimed isomorphism.

The second isomorphism is a consequence of the first and the universal coefficient theorem (Proposition 2.4 and Remark 2.15). □

Remark 3.3 If X is orientable, then the two eigenspaces of τ in the decomposition

$$(3-5) \quad H_T^*(\tilde{X}) = H_T^*(X) \oplus H_T^*(X; \tilde{\mathbb{k}})$$

are isomorphic as R –modules and even as modules over $H_T^*(X)$. Hence (co)homology with twisted coefficients and with constant coefficients are isomorphic in this case, and these isomorphisms are compatible with the two Poincaré duality isomorphisms $H_{T,c}^*(X) \rightarrow H_*^T(X)$ and $H_{T,c}^*(X; \tilde{\mathbb{k}}) \rightarrow H_*^T(X)$. Of course, in the case $\text{char } \mathbb{k} = 2$ there is no difference either.

3.2 Poincaré–Alexander–Lefschetz duality

Classically, Poincaré–Alexander–Lefschetz duality (also called “Poincaré–Lefschetz duality”) refers to an isomorphism of vector spaces

$$(3-6) \quad H_c^*(A, B) \cong H_{n-*}(X \setminus B, X \setminus A)$$

for any closed pair (A, B) in an oriented n –dimensional manifold X ; cf Dold [13, Section VIII.7] or Bredon [10, Section VI.8], for instance. In this section we generalize this to equivariant (co)homology, and we also derive a spectral sequence version of it. Our approach is similar to the one in [10]. We continue to assume that X is an n –dimensional \mathbb{k} –homology manifold with a T –action.

Our first result includes Theorem 1.1 from the introduction.

Theorem 3.4 (Poincaré–Alexander–Lefschetz duality) *Let (A, B) be a closed T –pair in X . Then there is a commutative diagram*

$$\begin{array}{ccccccc}
 \longrightarrow & H_{T,c}^{n-*}(A, B; \tilde{\mathbb{k}}) & \longrightarrow & H_{T,c}^{n-*}(A; \tilde{\mathbb{k}}) & \longrightarrow & H_{T,c}^{n-*}(B; \tilde{\mathbb{k}}) & \xrightarrow{d} & H_{T,c}^{n+1-*}(B; \tilde{\mathbb{k}}) & \longrightarrow \\
 & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
 \longrightarrow & H_*^T(X \setminus B, X \setminus A) & \longrightarrow & H_*^T(X, X \setminus A) & \longrightarrow & H_*^T(X, X \setminus B) & \xrightarrow{d} & H_{*-1}^T(X, X \setminus B) & \longrightarrow
 \end{array}$$

all of whose vertical arrows are isomorphisms. An analogous diagram exists with the roles of homology and cohomology interchanged and all arrows reversed.

Since we also want to prove an extension to spectral sequences, we place ourselves in a slightly more general situation. Consider an increasing filtration

$$(3-7) \quad \emptyset = X_{-1} \subset X_0 \subset \dots \subset X_m = X$$

of X by closed T –stable subsets. (See Remark 2.17 on how to do without the standing assumption of local contractability.) We set $\hat{X}_i = X \setminus X_i$, so that the decreasing filtration of X by the open complements of the X_i can be written as

$$(3-8) \quad X = \hat{X}_{-1} \supset \dots \supset \hat{X}_{m-1} \supset \hat{X}_m = \emptyset.$$

Let $\pi: \tilde{X} \rightarrow X$ be the orientation cover, and let $U = (U_{-1}, U_0, \dots, U_m)$ be an increasing sequence of open T –stable subsets of X such that $X \setminus U_{-1}$ is compact and $X_i \subset U_i$ for all i . Any such sequence determines an open cover

$$(3-9) \quad U = \{\pi^{-1}(U_0), \pi^{-1}(U_1 \setminus X_0), \dots, \pi^{-1}(U_m \setminus X_{m-1})\}$$

of \tilde{X} . We write $C^*(X | U; \tilde{\mathbb{k}})$ for the complex of U –small cochains and similarly $C_T^*(X | U; \tilde{\mathbb{k}}) = C^*(X | U; \tilde{\mathbb{k}}) \otimes R$ for the corresponding singular Cartan model. We start by establishing a variant of the cup product (3-1).

Lemma 3.5 *For any $-1 \leq i \leq j \leq m$ there is a well-defined relative cup product*

$$C_T^*(X, U_j; \tilde{\mathbb{k}}) \otimes C_T^*(\hat{X}_i) \xrightarrow{\cup} C_T^*(X | U; \tilde{\mathbb{k}}).$$

It is compatible with restrictions in the sense that the following diagram commutes:

$$\begin{array}{ccc}
 C_T^*(X, U_j; \tilde{\mathbb{k}}) \otimes C_T^*(\hat{X}_j) & \xrightarrow{\cup} & C_T^*(X | U; \tilde{\mathbb{k}}) \\
 \uparrow & & \uparrow = \\
 C_T^*(X, U_j; \tilde{\mathbb{k}}) \otimes C_T^*(\hat{X}_i) & \xrightarrow{\cup} & C_T^*(X | U; \tilde{\mathbb{k}}) \\
 \downarrow & & \downarrow = \\
 C_T^*(X, U_i; \tilde{\mathbb{k}}) \otimes C_T^*(\hat{X}_i) & \xrightarrow{\cup} & C_T^*(X | U; \tilde{\mathbb{k}})
 \end{array}$$

Proof The product of $\alpha \otimes f \in C_T^*(X, U_j; \tilde{\mathbb{k}})$ and $\beta \otimes g \in C_T^*(\hat{X}_i)$ is defined by

$$(3-10) \quad (\alpha \otimes f) \cup (\beta \otimes g) = \alpha \cup \pi^*(\hat{\beta}) \otimes fg,$$

where $\hat{\beta} \in C^*(X)$ is a preimage of β .

To show that this is well-defined, consider a \mathcal{U} -small singular simplex σ in \tilde{X} . If σ lies in $\pi^{-1}(U_j)$, then so does any face σ' of it. Hence $\alpha(\sigma') = 0$ and therefore $(\alpha \cup \pi^*(\hat{\beta}))(\sigma) = 0$. If σ does not lie in $\pi^{-1}(U_j)$, then it lies in $\pi^{-1}(\hat{X}_i) \supset \pi^{-1}(\hat{X}_j)$ since it is \mathcal{U} -small, and $(\alpha \cup \pi^*(\hat{\beta}))(\sigma)$ is again independent of the choice of $\hat{\beta}$.

The commutativity of the diagram is clear by construction. □

For $i \leq j$, write

$$(3-11) \quad \bar{C}_{T,c}^*(X_j, X_i; \tilde{\mathbb{k}}) = \varinjlim C_T^*(U_j, U_i; \tilde{\mathbb{k}})$$

where the direct limit is taken over all open covers \mathcal{U} induced by sequences U as above, and let $\bar{C}_*^{T,c}(X_j, X_i; \tilde{\mathbb{k}})$ be the R -dual complex. Note that for $i \leq j \leq k$ we have short exact sequences

$$(3-12) \quad 0 \rightarrow \bar{C}_{T,c}^*(X_k, X_j; \tilde{\mathbb{k}}) \rightarrow \bar{C}_{T,c}^*(X_k, X_i; \tilde{\mathbb{k}}) \rightarrow \bar{C}_{T,c}^*(X_j, X_i; \tilde{\mathbb{k}}) \rightarrow 0,$$

and the canonical maps

$$\bar{C}_{T,c}^*(X_j, X_i; \tilde{\mathbb{k}}) \rightarrow C_{T,c}^*(X_j, X_i; \tilde{\mathbb{k}}) \quad \text{and} \quad C_*^{T,c}(X_j, X_i; \tilde{\mathbb{k}}) \rightarrow \bar{C}_*^{T,c}(X_j, X_i; \tilde{\mathbb{k}})$$

are quasi-isomorphisms by tautness.

By passing to the direct limit in Lemma 3.5, we get the family of relative cup products

$$(3-13) \quad \bar{C}_{T,c}^*(X, X_i; \tilde{\mathbb{k}}) \otimes C_T^*(\hat{X}_i) \xrightarrow{\cup} \bar{C}_{T,c}^*(X; \tilde{\mathbb{k}}).$$

Fix a representative $c_T \in \bar{C}_n^{T,c}(X; \tilde{\mathbb{k}})$ of the equivariant orientation $o_T \in H_n^{T,c}(X; \tilde{\mathbb{k}})$. Composition of (3-13) with c_T yields a pairing $\bar{C}_{T,c}^*(X, X_i; \tilde{\mathbb{k}}) \otimes C_T^*(\hat{X}_i) \rightarrow R$, which we interpret as a map

$$(3-14) \quad f_i: \bar{C}_{T,c}^*(X, X_i; \tilde{\mathbb{k}}) \rightarrow C_*^T(\hat{X}_i).$$

Lemma 3.6 *The map (3-14) is a quasi-isomorphism. Moreover, for $i \leq j$ it leads to a commutative diagram*

$$\begin{array}{ccccccc} 0 & \longrightarrow & \bar{C}_{T,c}^*(X, X_j; \tilde{\mathbb{k}}) & \longrightarrow & \bar{C}_{T,c}^*(X, X_i; \tilde{\mathbb{k}}) & \longrightarrow & \bar{C}_{T,c}^*(X_j, X_i; \tilde{\mathbb{k}}) \longrightarrow 0 \\ & & \downarrow f_j & & \downarrow f_i & & \downarrow f_{ji} \\ 0 & \longrightarrow & C_*^T(\hat{X}_j) & \longrightarrow & C_*^T(\hat{X}_i) & \longrightarrow & C_*^T(\hat{X}_i, \hat{X}_j) \longrightarrow 0 \end{array}$$

whose rows are exact and whose induced map f_{ji} is a quasi-isomorphisms as well.

Proof The exactness of the top row in the diagram was already observed in (3-12). The compatibility of relative cup products with restrictions stated in Lemma 3.5 implies that the left square in the diagram commutes, which induces the right vertical arrow.

Note that Proposition 2.9 remains valid for twisted coefficients, and that the diagram

$$(3-15) \quad \begin{array}{ccc} H_{T,c}^*(X, X_i; \tilde{\mathbb{k}}) \otimes H_*^{T,c}(X, X_i; \tilde{\mathbb{k}}) & \longrightarrow & R \\ \cong \downarrow & & \downarrow = \\ H_{T,c}^*(\hat{X}_i; \tilde{\mathbb{k}}) \otimes H_*^{T,c}(\hat{X}_i; \tilde{\mathbb{k}}) & \longrightarrow & R \end{array}$$

is commutative. Moreover, the restriction of the orientation o_T to any component of \hat{X}_i is again an orientation. Hence the map (3-14) corresponds to the map

$$H_{T,c}^*(\hat{X}_i; \tilde{\mathbb{k}}) \rightarrow H_*^T(\hat{X}_i),$$

which is an isomorphism by Proposition 3.2.

Coming back to the commutative ladder, two out of the three maps between the corresponding long exact sequences in (co)homology are isomorphisms, hence so is the third. \square

Proof of Theorem 3.4 Consider the filtration $\emptyset \subset B \subset A \subset X$ of X and the associated diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \bar{C}_{T,c}^*(A, B; \tilde{\mathbb{k}}) & \longrightarrow & \bar{C}_{T,c}^*(A; \tilde{\mathbb{k}}) & \longrightarrow & \bar{C}_{T,c}^*(B; \tilde{\mathbb{k}}) \longrightarrow 0 \\ & & \downarrow f_{AB} & & \downarrow f_A & & \downarrow f_B \\ 0 & \longrightarrow & C_*^T(X \setminus B, X \setminus A) & \longrightarrow & C_*^T(X, X \setminus A) & \longrightarrow & C_*^T(X, X \setminus B) \longrightarrow 0 \end{array}$$

whose top row is again of the form (3-12). The maps f_A and f_B are special cases of the map f_{ji} from Lemma 3.6. It follows from their definition that the right square commutes, which induces the map f_{AB} . By passing to (co)homology we get the commutative ladder stated in Theorem 3.4. Since $H^*(f_A)$ and $H^*(f_B)$ are isomorphisms by Lemma 3.6, so is $H^*(f_{AB})$. This proves the first part of the theorem.

The analogous result with the roles of (co)homology reversed is obtained by applying the functor $\text{Hom}_R(-, R)$ to the diagram above. Because the short sequences in the diagram split over R , their duals remain exact. Moreover, the natural inclusion of $C_T^*(A, B)$ into its double dual is a chain homotopy equivalence. This follows from the fact that for the chain-equivalent minimal Hirsch–Brown model, which is free and finitely generated over R , the corresponding map is even an isomorphism. \square

A spectral sequence version of equivariant Poincaré–Alexander–Lefschetz duality is as follows:

Proposition 3.7 *Let $o_T \in H_n^{T,c}(X; \tilde{\mathbb{k}})$ be an equivariant orientation of X . Taking the cap product with o_T induces an isomorphism (of degree $-n$) from the E_1 page on between the spectral sequences*

$$\begin{aligned} E_1^p &= H_{T,c}^*(X_p, X_{p-1}; \tilde{\mathbb{k}}) \Rightarrow H_{T,c}^*(X; \tilde{\mathbb{k}}), \\ E_1^p &= H_*^T(\hat{X}_{p-1}, \hat{X}_p) \Rightarrow H_*^T(X). \end{aligned}$$

Similarly, the spectral sequences

$$\begin{aligned} E_1^p &= H_*^{T,c}(X_p, X_{p-1}; \tilde{\mathbb{k}}) \Rightarrow H_*^{T,c}(X; \tilde{\mathbb{k}}), \\ E_1^p &= H_T^*(\hat{X}_{p-1}, \hat{X}_p) \Rightarrow H_T^*(X) \end{aligned}$$

are isomorphic from the E_1 page on.

Proof We filter $\bar{C}_{T,c}^*(X; \tilde{\mathbb{k}})$ by $\mathcal{F}_i = \bar{C}_{T,c}^*(X, X_{i-1}; \tilde{\mathbb{k}})$ for $0 \leq i \leq m$ and similarly $C_*^T(X)$ by $\hat{\mathcal{F}}_i = C_*^T(\hat{X}_{i-1})$.

We know from Lemma 3.6 that the diagram

$$(3-16) \quad \begin{array}{ccc} \mathcal{F}_j = \bar{C}_{T,c}^*(X, X_j; \tilde{\mathbb{k}}) & \longrightarrow & C_*^T(\hat{X}_j) = \hat{\mathcal{F}}_j \\ \downarrow & & \downarrow \\ \mathcal{F}_i = \bar{C}_{T,c}^*(X, X_i; \tilde{\mathbb{k}}) & \longrightarrow & C_*^T(\hat{X}_i) = \hat{\mathcal{F}}_i \end{array}$$

commutes for $i \leq j$, so that we obtain a map of spectral sequences with

$$(3-17) \quad E_0^i(\mathcal{F}) = \bar{C}_{T,c}^*(X_i, X_{i-1}; \tilde{\mathbb{k}}) \rightarrow E_0^i(\hat{\mathcal{F}}) = C_*^T(\hat{X}_{i-1}, \hat{X}_i),$$

$$(3-18) \quad E_1^i(\mathcal{F}) = H_{T,c}^*(X_i, X_{i-1}; \tilde{\mathbb{k}}) \rightarrow E_1^i(\hat{\mathcal{F}}) = H_*^T(\hat{X}_{i-1}, \hat{X}_i).$$

It follows as in the proof of Theorem 3.4 that the map (3-18) is an isomorphism. The second part follows analogously by dualizing (3-14) and the filtrations \mathcal{F} and $\hat{\mathcal{F}}$. \square

Equipped with equivariant Poincaré–Alexander–Lefschetz duality, we can easily deduce the following result, which is asserted in [9, page 849] without proof.

Corollary 3.8 *If X is orientable and T acts locally freely, then X/T is an orientable \mathbb{k} –homology manifold of dimension $n - r$.*

Proof As discussed in Remark 2.1, X/T satisfies our assumption on spaces, and it is connected since X is.

To verify condition (2-36), take an $x \in X$ with image $\bar{x} \in \bar{X} = X/T$. By Proposition 2.7 and Poincaré–Alexander–Lefschetz duality for the T -pair (Tx, \emptyset) in X , we have

$$(3-19) \quad \begin{aligned} H_i(\bar{X}, \bar{X} \setminus \{\bar{x}\}) &= H_{i+r}^T(X, X \setminus Tx) \cong H_{T,c}^{n-r-i}(Tx) \\ &= H_c^{n-r-i}(\{\bar{x}\}) = \begin{cases} \mathbb{k} & \text{if } i = n - r, \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

Again by Proposition 2.7, the equivariant orientation $o_T \in H_n^{T,c}(X)$ descends to a non-zero element in $H_{n-r}^c(X/T)$. Hence X/T is orientable. \square

Example 3.9 A simple example shows why orientability is needed in Corollary 3.8 above. Let X be the open Möbius band with its standard locally free action of $T = S^1$. Then X/T is a half-open interval, and so it is not a (homology) manifold, but rather a manifold with boundary. The quotient \tilde{X}/T of the orientation cover looks like the letter “V” with its vertex corresponding to the end point of the interval, which in turn corresponds to the middle circle, the only non-free orbit.

Remark 3.10 Let (A, B) be a closed T -pair in X . In Proposition 2.7 we established an isomorphism of $H^*(BL)$ -modules

$$(3-20) \quad H_*^T(A, B) = H_{*-p}^L(A/K, B/K)$$

whenever a subtorus $K \subset T$ of rank p and with quotient $L = T/K$ acts freely on $A \setminus B$; a locally free action was sufficient in case $\text{char } \mathbb{k} = 0$. In the context of orientable homology manifolds, we can now understand this isomorphism in terms of Poincaré–Alexander–Lefschetz duality:

Assume that K acts freely (or just locally freely if $\text{char } \mathbb{k} = 0$) on the orientable homology manifold X , so that X/K is again an orientable homology manifold by Corollary 3.8. Let $n = \dim X = \dim X/K + p$. Using the cohomological part of Proposition 2.7 and Poincaré–Alexander–Lefschetz duality, we get

$$(3-21) \quad H_*^T(A, B) = H_{T,c}^{n-*}(X \setminus B, X \setminus A)$$

$$(3-22) \quad = H_{L,c}^{n-*}((X \setminus B)/K, (X \setminus A)/K) = H_{*-p}^L(A/K, B/K).$$

Hence the isomorphism (3-20) can be interpreted as a push-forward map or integration over the fibre in this setting.

3.3 Thom isomorphism

As in the non-equivariant case, the Thom isomorphism is a consequence of Poincaré and Poincaré–Alexander–Lefschetz duality; cf [13, Section VIII.7, Section VIII.11]. In fact, one can use our version of equivariant duality to define also Gysin homomorphisms (push forwards), indices, Euler classes etc. in the equivariant setting and to prove their main properties (cf [4, Section 5.3]) for cohomology with different supports. The use of the Cartan model even provides a more functorial approach than the minimal Hirsch–Brown model used in [4]. Here we only develop the theory as far as needed for our applications in Section 4.2.

We continue to assume that X is an n -dimensional \mathbb{k} -homology manifold with a T -action.

Proposition 3.11 (1) *Let $Y \subset X$ be a closed T -stable \mathbb{k} -homology manifold of dimension m . Suppose that the orientation cover of X restricts to the orientation cover of Y . Then there is an isomorphism of R -modules $H_T^*(X, X \setminus Y) \cong H_T^*(Y)$ of degree $m - n$.*

(2) *Assume $\text{char } \mathbb{k} = 0$, and let $K \subset T$ be a subtorus. Then there is an isomorphism of R -modules $H_T^*(X, X \setminus X^K) \cong H_T^*(X^K)$. This isomorphism has degree $m - n$ if all components of X^K are of dimension m ; in general it only preserves degrees mod 2.*

Proof We start with the first case. By Poincaré–Alexander–Lefschetz duality for the pair (X, Y) and Poincaré duality for Y we have isomorphisms of R -modules

$$(3-23) \quad H_T^*(X, X \setminus Y) \cong H_*^{T,c}(Y, \tilde{\mathbb{k}}) \cong H_T^*(Y),$$

whose composition has degree $m - n$. Note that for the first isomorphism $H_*^{T,c}(Y, \tilde{\mathbb{k}})$ is defined via the restriction of the orientation cover of X , and via the orientation cover for Y in the second isomorphism. By assumption, these two covers coincide.

We now consider the fixed point set X^K . It has finitely many components, say Y_1, \dots, Y_k , which are \mathbb{k} -homology manifolds whose dimensions are congruent to n mod 2 by a result of Conner and Floyd [6, Theorem V.3.2]. By excision we have

$$(3-24) \quad H_T^*(X, X \setminus X^K) = \bigoplus_i H_T^*(X, X \setminus Y_i).$$

The claim follows once we know that the restriction of an orientation cover for X to each Y_i is an orientation cover for that component. This is the content of the following lemma. □

Lemma 3.12 *Assume $\text{char } \mathbb{k} = 0$. Then the restriction of an orientation cover for X to any component Y of X^T is an orientation cover for Y .*

Note that each component Y is orientable if and only if its orientation cover is trivial. According to the theorem of Conner and Floyd mentioned previously, each component Y of X^T is orientable if X is so. Lemma 3.12 can therefore be seen as a generalization of this part of their result. Also note that for a smooth T -manifold X , Lemma 3.12 is a consequence of the fact that the normal bundle of each component Y of X^T is orientable (cf [14, Corollary 2]): By excision one can restrict from X to a T -stable tubular neighbourhood of Y , and, like the normal bundle, this neighbourhood is orientable if and only if Y is.

Proof Let $\tilde{X} \rightarrow X$ be an orientation cover for X and $\tilde{Z} \rightarrow Z$ its restriction to $Z = X^T$. Note that $\tilde{Z} = (\tilde{X})^T$. For each component Y of Z , say of dimension m , let $\tilde{Y} \rightarrow Y$ be the further restriction. We will show $H_m^c(\tilde{Y})_- \neq 0$, which proves that $\tilde{Y} \rightarrow Y$ is an orientation cover of Y : If Y is orientable, this condition ensures that \tilde{Y} is disconnected, and if Y is non-orientable, it shows that \tilde{Y} is orientable.

Since the cap product (3-2) is natural with respect to proper maps of spaces, we get a commutative diagram

$$(3-25) \quad \begin{array}{ccc} H_{T,c}^*(\tilde{X})_- & \xrightarrow{\cap \iota_*(b)} & H_*^T(\tilde{X})_+ \\ \iota_* \downarrow & & \uparrow \iota_* \\ H_{T,c}^*(\tilde{Z})_- & \xrightarrow{\cap b} & H_*^T(\tilde{Z})_+ \end{array}$$

where $\iota: \tilde{Z} \hookrightarrow \tilde{X}$ and $b \in H_*^{T,c}(\tilde{Z})_-$. Note that $\iota_*: H_*^c(\tilde{Z}) \rightarrow H_*^c(\tilde{X})$ commutes with the involution τ and therefore preserves the ± 1 eigenspaces. Let $S \subset R$ be the multiplicative subset of homogeneous polynomials of positive degree. We localize the diagram at S and choose b to be a preimage of $o_T \in S^{-1}H_*^T(\tilde{X})_-$, which is possible by the localization theorem in equivariant homology (Proposition 2.5, here for homology with closed supports). By the same result and equivariant Poincaré duality, this turns the top and vertical arrows into isomorphisms, hence also the bottom arrow.

Now $b \in S^{-1}H_*^{T,c}(\tilde{Z})_-$ is a sum of elements, one for each component of $Z = X^T$. The summand b^Y corresponding to the component Y can be written in the form

$$(3-26) \quad b^Y = b_m^Y + \dots + b_0^Y \in S^{-1}H_*^{T,c}(\tilde{Y})_- = H_*^c(\tilde{Y})_- \otimes S^{-1}R$$

for some $b_i^Y \in H_i^c(\tilde{Y})_- \otimes S^{-1}R$. A cap product $\alpha \cap c$ with $\alpha \in H^m(\tilde{Y})$ and $c \in H_i^c(\tilde{Y})$ vanishes unless $i = m$. Because capping with b^Y is an isomorphism, we conclude that $b_m^Y \neq 0$, hence $H_m^c(Y)_- \neq 0$. □

4 Applications to the orbit structure

We assume throughout the rest of this paper that X is a T –space and that the characteristic of the field \mathbb{k} is 0. Recall that the orbit filtration (X_i) has been defined in the introduction.

4.1 General T –spaces

In [3, Sections 4, 5.1 and 5.2] we established results about the equivariant cohomology with closed supports and equivariant homology with compact supports of the orbit filtration of a T –space X . All these results have analogues for the other pair of supports, ie for cohomology with compact supports and homology with closed supports. Moreover, for a \mathbb{k} –homology manifold X , one has another set of analogous results for (co)homology with twisted coefficients. The proofs for the new cases are usually identical to the ones given in [3]. In the case of twisted coefficients, one may alternatively derive them from the decompositions (2-44) and (2-45) and the untwisted result for an orientation cover; see Proposition 4.1 below for an example. We therefore content ourselves by stating the most important results in a more general setting. All results in this section are equally valid for the other pair of supports.

We simplify notation in the following way: For a T –pair (A, B) in a homology manifold X we write $H_T^*(A, B; \ell)$ to denote either cohomology with constant coefficients ($\ell = \mathbb{k}$) or with twisted coefficients ($\ell = \tilde{\mathbb{k}}$). The same applies to homology and (co)chain complexes. If X is not a homology manifold, then ℓ always means constant coefficients.

Proposition 4.1 *The R –modules $H_T^*(X_i, X_{i-1}; \ell)$ and $H_*^T(X_i, X_{i-1}; \ell)$ are zero or Cohen–Macaulay of dimension $r - i$ for $0 \leq i \leq r$.*

Proof The version for constant coefficients and the usual pair of supports is proved in [3, Proposition 4.2], following the ideas of [5, Section 7]. The proof for the other pair of supports is identical. The case of twisted coefficients follows from the untwisted version for an orientation cover and the observation that a non-zero direct summand of a Cohen–Macaulay module is again Cohen–Macaulay of the same dimension. \square

Corollary 4.2 *The spectral sequence associated with the orbit filtration of $C_*^T(X; \ell)$ and converging to $H_*^T(X; \ell)$ degenerates at $E_p^1 = H_*^T(X_p, X_{p-1}; \ell)$.*

Proof See [3, Corollary 4.4]. \square

The following two results are immediate consequences of Corollary 4.2; cf [3, Corollary 4.6]. For the convenience of the reader, we provide proofs that are based only on the crucial Cohen–Macaulay property identified in Proposition 4.1.

Proposition 4.3 *For any $-1 \leq i < j \leq r$ there is a short exact sequence*

$$0 \rightarrow H_*^T(X_j, X_i; \ell) \rightarrow H_*^T(X, X_i; \ell) \rightarrow H_*^T(X, X_j; \ell) \rightarrow 0.$$

Proposition 4.4 *$\text{Ext}_R^p(H_*^T(X_j, X_i; \ell), R) = 0$ for $p > j$ and $p \leq i$. In other words, $\dim_R H_*^T(X_j, X_i; \ell) \leq r - i - 1$ and $\text{depth}_R H_*^T(X_j, X_i; \ell) \geq r - j$.*

Proof of Propositions 4.3 and 4.4 We prove both statements simultaneously by falling induction on i . For $i = r$ there is nothing to show.

Now assume both claims are true for a given i and all $j \geq i$. By Proposition 4.1, $H_*^T(X_i, X_{i-1}; \ell)$ is zero or Cohen–Macaulay of dimension $r - i$. Because $H_*^T(X, X_i; \ell)$ is of dimension at most $r - i - 1$ by induction, the connecting homomorphism

$$(4-1) \quad H_*^T(X, X_i; \ell) \rightarrow H_{*-1}^T(X_i, X_{i-1}; \ell)$$

is zero (cf [3, Lemma 2.2]), so that we get the short exact sequence

$$(4-2) \quad 0 \rightarrow H_*^T(X_i, X_{i-1}; \ell) \rightarrow H_*^T(X, X_{i-1}; \ell) \rightarrow H_*^T(X, X_i; \ell) \rightarrow 0.$$

By induction, the map $H_*^T(X, X_i; \ell) \rightarrow H_*^T(X, X_j; \ell)$ is surjective, hence so is the composition

$$(4-3) \quad H_*^T(X, X_{i-1}; \ell) \rightarrow H_*^T(X, X_i; \ell) \rightarrow H_*^T(X, X_j; \ell),$$

which proves the first claim. Taking $X = X_j$ in (4-2), we obtain

$$(4-4) \quad 0 \rightarrow H_*^T(X_i, X_{i-1}; \ell) \rightarrow H_*^T(X_j, X_{i-1}; \ell) \rightarrow H_*^T(X_j, X_i; \ell) \rightarrow 0.$$

The second claim now follows by induction and the way Ext modules (or dimension and depth/projective dimension) behave with respect to short exact sequences. \square

The spectral sequence for equivariant cohomology induced by the orbit filtration does *not* degenerate at the E_1 page in general. Since this page of the spectral sequence is of independent interest, we give it a name.

The *non-augmented Atiyah–Bredon complex* $AB^*(X; \ell)$ with coefficients in ℓ is the complex of R -modules defined by

$$(4-5) \quad AB^i(X; \ell) = H_T^{*+i}(X_i, X_{i-1}; \ell)$$

for $0 \leq i \leq r$ and zero otherwise. The differential

$$(4-6) \quad d_i: H_T^*(X_i, X_{i-1}; \ell) \rightarrow H_T^{*+1}(X_{i+1}, X_i; \ell)$$

is the connecting map in the long exact sequence of the triple (X_{i+1}, X_i, X_{i-1}) . Note that $AB^*(X; \ell)$ is the E_1 page of the spectral sequence arising from the orbit filtration of X and converging to $H_T^*(X; \ell)$, and its cohomology $H^*(AB^*(X; \ell))$ is the E_2 page.

The *augmented Atiyah–Bredon complex* is obtained by augmenting $AB^*(X; \ell)$ by $AB^{-1}(X; \ell) = H_T^*(X; \ell)$ and the restriction to the fixed point set,

$$(4-7) \quad 0 \rightarrow H_T^*(X; \ell) \rightarrow H_T^*(X_0; \ell) \xrightarrow{d_0} H_T^{*+1}(X_1, X_0; \ell) \xrightarrow{d_1} \dots \\ \xrightarrow{d_{r-1}} H_T^{*+r}(X_r, X_{r-1}; \ell) \rightarrow 0.$$

Remark 4.5 This sequence first appeared explicitly in the paper [9] of Bredon, but it goes back to work of Atiyah [5, Section 7]. In the context of equivariant K –theory, Atiyah showed that the freeness of $K_T^*(X)$ implies that the sequence

$$(4-8) \quad 0 \rightarrow K_T^*(X, X_{i-1}) \rightarrow K_T^*(X_i, X_{i-1}) \rightarrow K_T^*(X, X_i) \rightarrow 0$$

is exact for all i [5, Equation (7.3)]. This in turn is equivalent to the exactness of the K –theoretic analogue of (4-7); cf Franz and Puppe [17, Lemma 4.1]. Atiyah actually considered representations only, but his arguments work for any T –space.

It turns out that the cohomology of the non-augmented Atiyah–Bredon complex is completely determined by $H_*^T(X; \ell)$.

Theorem 4.6 For any T –space X the following two spectral sequences converging to $H_T^*(X; \ell)$ are naturally isomorphic from the E_2 page on:

- (1) The one induced by the orbit filtration with $E_1^p = H_T^*(X_p, X_{p-1}; \ell)$
- (2) The universal coefficient spectral sequence with $E_2^p = \text{Ext}_R^p(H_*^T(X; \ell), R)$

Proof See [3, Theorem 4.8]. The version for twisted coefficients may again be derived from the untwisted result for an orientation cover. □

Corollary 4.7 For any $i \geq 0$ there is an isomorphism of R –modules

$$H^i(AB^*(X; \ell)) = \text{Ext}_R^i(H_*^T(X; \ell), R).$$

In Section 5 we will give a direct proof of this important result that is not based on Theorem 4.6.

Theorem 4.8 *The following conditions are equivalent for any $0 \leq j \leq r$:*

- (1) *The Atiyah–Bredon sequence (4-7) is exact at all positions $-1 \leq i \leq j - 2$.*
- (2) *The restriction map $H_T^*(X; \ell) \rightarrow H_K^*(X; \ell)$ is surjective for all subtori K of T of rank $r - j$.*
- (3) *$H_T^*(X; \ell)$ is free over all subrings $H^*(BL) \subset H^*(BT) = R$, where L is a quotient of T of rank j .*
- (4) *$H_T^*(X; \ell)$ is a j^{th} syzygy.*

Several equivalent definitions of syzygies are collected in [3, Section 2.3].

Proof The proof of [3, Theorem 5.7] carries over. Only the argument for the equivalence (2) \Leftrightarrow (3) has to be slightly modified in the case of twisted coefficients: The involution on an orientation cover \tilde{X} induces one on the Borel construction \tilde{X}_T , and $H_T^*(X; \tilde{\mathbb{k}}) = H^*(\tilde{X}_T)_-$ in the notation of Section 2.6, and analogously for K . (Note that the decomposition of the cohomology into the ± 1 eigenspaces of the involution exists even for spaces that do not satisfy our standing assumptions.) Now one considers the map

$$(4-9) \quad H_T^*(X; \tilde{\mathbb{k}}) = H_{T/K}^*(\tilde{X}_K)_- \rightarrow H^*(\tilde{X}_K)_- = H_K^*(X; \tilde{\mathbb{k}}),$$

and applies the Leray–Hirsch argument as used in [3] to the -1 eigenspaces. □

4.2 Homology manifolds

In this section we assume that X is a \mathbb{k} –homology manifold. Theorem 4.6 and [3, Theorem 4.8] may be combined with Poincaré duality and Poincaré–Alexander–Lefschetz duality in various ways. The following result is an example of this. Recall that $\hat{X}_i = X \setminus X_i$.

Corollary 4.9 *The following spectral sequences are isomorphic from the E_2 page on:*

$$\begin{aligned} E_1^p &= H_*^T(\hat{X}_{p-1}, \hat{X}_p) \Rightarrow H_*^T(X) \\ E_2^p &= \text{Ext}_R^p(H_T^*(X), R) \Rightarrow H_*^T(X) \end{aligned}$$

Proof Let $n = \dim X$. By Proposition 3.7, the first spectral sequence is isomorphic, from the E_1 page on, to the spectral sequence

$$(4-10) \quad E_1^p = H_{T,c}^*(X_p, X_{p-1}; \tilde{\mathbb{k}})[-n] \Rightarrow H_{T,c}^*(X; \tilde{\mathbb{k}})[-n].$$

By Poincaré duality, the second spectral sequence is isomorphic to

$$(4-11) \quad E_2^p = \text{Ext}_R^p(H_*^{T,c}(X; \tilde{\mathbb{k}}), R)[-n] \Rightarrow H_{T,c}^*(X; \tilde{\mathbb{k}})[-n].$$

Hence the claim follows from Theorem 4.6. □

Proposition 4.10 For any $0 \leq i \leq r$ there is an isomorphism of R –modules

$$H_T^*(\widehat{X}_{i-1}, \widehat{X}_i) \cong H_T^*(X_i \setminus X_{i-1}),$$

preserving degrees modulo 2.

Proof Since only finitely many isotropy groups occur in X , there is a subtorus $K \subset T$ such that $\widehat{X}_{i-1}^K = X_i \setminus X_{i-1}$. Hence our claim reduces to the Thom isomorphism from Proposition 3.11. \square

The following result generalizes a theorem of Duflot [14, Theorem 1] concerning smooth actions on differential manifolds. More than the extension to continuous actions on homology manifolds, our main insight is that Duflot’s result follows by equivariant Poincaré–Alexander–Lefschetz duality from Proposition 4.3, which is valid for *all* T –spaces.

Proposition 4.11 For any $0 \leq i \leq r$ there are short exact sequences

$$\begin{aligned} 0 \rightarrow H_T^*(X, \widehat{X}_i) \rightarrow H_T^*(X) \rightarrow H_T^*(\widehat{X}_i) \rightarrow 0 \\ 0 \rightarrow H_T^*(X, \widehat{X}_{i-1}) \rightarrow H_T^*(X, \widehat{X}_i) \rightarrow H_T^*(X_i \setminus X_{i-1}) \rightarrow 0 \end{aligned}$$

where the right map in the lower sequence preserves degrees only mod 2.

Duflot also considers actions of p –tori $(\mathbb{Z}_p)^r$ with $p > 2$. The results of [3] and this paper can as well be extended to p –tori; we will elaborate on this elsewhere because some proofs require modification.

Proof By Proposition 4.3 we have a short exact sequence

$$(4-12) \quad 0 \rightarrow H_*^T(X_i; \widetilde{\mathbb{k}}) \rightarrow H_*^T(X; \widetilde{\mathbb{k}}) \rightarrow H_*^T(X, X_i; \widetilde{\mathbb{k}}) \rightarrow 0.$$

The first short exact sequence we are claiming follows from this by Poincaré–Alexander–Lefschetz duality (Theorem 3.4).

Replacing X_i by X_{i-1} and X_j by X_i in Proposition 4.3 leads similarly to the short exact sequence

$$(4-13) \quad 0 \rightarrow H_T^*(X, \widehat{X}_{i-1}) \rightarrow H_T^*(X, \widehat{X}_i) \rightarrow H_T^*(\widehat{X}_{i-1}, \widehat{X}_i) \rightarrow 0.$$

Combining this with Proposition 4.10 confirms our second claim. \square

Not surprisingly, we also get the following spectral sequence version:

Proposition 4.12 *The spectral sequence associated to the filtration (\widehat{X}_i) and converging to $H_T^*(X)$ degenerates at the E_1 page.*

Proof By Proposition 3.7, this spectral sequence is isomorphic, from the E_1 page on, to the spectral sequence converging to $H_*^{T,c}(X; \widetilde{\mathbb{K}})$ with $E_1^p = H_*^{T,c}(X_p, X_{p-1}; \widetilde{\mathbb{K}})$. The latter degenerates by Corollary 4.2. \square

4.3 Uniform actions

Let X be a T -space. For dimensional reasons, it follows from Proposition 4.1 that the differential

$$(4-14) \quad d_i: H_T^*(X_i, X_{i-1}) \rightarrow H_T^{*+1}(X_{i+1}, X_i)$$

cannot be injective unless $H_T^*(X_i, X_{i-1}) = 0$. This has implications for the uniformity of actions, which we discuss now.

Recall from [4, Definition 3.6.17] that the T -action on X is said to be *uniform* if for any subtorus $K \subset T$ and any component F of X^K one has $F^T \neq \emptyset$. (This implies $X^T \neq \emptyset$ if $X \neq \emptyset$.)

We call F a *minimal stratum* of X corresponding to the subtorus $K \subset T$ if F is a component of X^K and if $F^L = \emptyset$ for any subtorus L properly containing K . Note that the action is uniform if and only if all minimal strata are components of X^T . This observation makes it easy to construct non-uniform actions, even in the context of compact orientable manifolds with fixed points; see [2, Example 1.7.4].

It has been noted by a number of authors that the T -action is uniform if $H_T^*(X)$ is a free R -module. A large part of [3], however, is concerned with the case where $H_T^*(X)$ is a torsion-free R -module (that is, a first syzygy), but not necessarily free. So we note the following, which is also an immediate consequence of the characterization of uniform actions given in [4, Theorem 3.6.18].

Proposition 4.13 *If $H_T^*(X)$ is R -torsion-free, then the action is uniform.*

Proof Assume that there is a minimal stratum F , corresponding to a subtorus $K \subsetneq T$. Then $H_T^*(F)$ is a direct summand of $H_T^*(X^K)$. Set $S = H^*(BK) \setminus \{0\}$ and $\widetilde{S} = R \setminus \{0\}$. By the localization theorem, we have

$$(4-15) \quad S^{-1}H_T^*(X) \cong S^{-1}H_T^*(X^K) = S^{-1}H_T^*(F) \oplus S^{-1}H_T^*(X^K \setminus F),$$

so we can choose a $c \in H_T^*(X)$ such that its image in $S^{-1}H_T^*(X^K)$ is non-zero and lies in $S^{-1}H_T^*(F)$. Because F^T is empty, $H_T^*(F)$ is R -torsion. This implies that

the image of c in $\tilde{S}^{-1} H_T^*(X^T)$ is zero, hence also the one in $H_T^*(X^T)$. But this is a contradiction because the torsion-freeness of $H_T^*(X)$ is equivalent to the injectivity of the map $H_T^*(X) \rightarrow H_T^*(X^T)$. \square

Proposition 4.14 *Let F be a minimal stratum of X corresponding to a subtorus $K \subset T$ of rank $r - i$. Then $H^i(AB^*(X)) \neq 0$.*

Proof The minimal stratum F is a component of both $X_i \setminus X_{i-1}$ and $X_i \setminus X_{i-2}$. So the summand $H_T^*(F)$ maps isomorphically under the restriction $H_T^*(X_i, X_{i-1}) \rightarrow H_T^*(X_i, X_{i-2})$, and $H_T^*(F) \cap \text{im } d_{i-1} = 0$. On the other hand, $\dim_R H_T^*(F) = r - i$. Because $H_T^*(X_{i+1}, X_i)$ is of dimension $r - i - 1$, the restriction of the differential to $H_T^*(F)$ cannot be injective. \square

Proposition 4.14 also follows from [4, Theorem 3.6.14]. For another result relating the uniformity and torsion-freeness, see [4, Theorem 3.8.7 (4)]. In the notation of that theorem, a minimal stratum $F = c$ corresponding to a subtorus $K \subset T$ gives one of the pairs (K_i, c_i) , $1 \leq i \leq \gamma$.

5 The cohomology of the Atiyah–Bredon complex

In this section we shall give a direct proof of Corollary 4.7. Instead of reasoning with spectral sequences, we will rely on Propositions 4.3 and 4.4. Our proof is valid for any pair of supports and, in case of a \mathbb{k} -homology manifold, also for twisted coefficients. For ease of notation, we write it down only for constant coefficients and the usual pair of supports. Recall that we are still assuming the characteristic of \mathbb{k} to be 0. For convenience, we define $X_{r+1} = X$ in addition to $X_{-1} = \emptyset$.

Let $0 \leq i \leq r$. The following commutative diagram with exact rows will play a central role:

$$\begin{array}{ccccccc}
 0 & \longrightarrow & H_*^T(X_i) & \longrightarrow & H_*^T(X_{i+1}) & \longrightarrow & H_*^T(X_{i+1}, X_i) \longrightarrow 0 \\
 (5-1) & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & H_*^T(X_i, X_{i-1}) & \longrightarrow & H_*^T(X_{i+1}, X_{i-1}) & \longrightarrow & H_*^T(X_{i+1}, X_i) \longrightarrow 0
 \end{array}$$

The exactness of the top row is Proposition 4.3 for the triple (X_{i+1}, X_i, X_{-1}) , and that of the bottom follows by looking at (X_{i+1}, X_i, X_{i-1}) .

For brevity, we denote $H_*^T(X_j, X_i)$ by $M_{j,i}$ and, for any R -module M , we abbreviate $\text{Ext}_R^p(M, R)[p]$ by $\mathcal{E}^p(M)$. From the bottom row of (5-1) and the long exact sequence

for Ext we have a connecting homomorphism

$$(5-2) \quad \mathcal{E}^i(M_{i,i-1}) \xrightarrow{\delta_i} \mathcal{E}^{i+1}(M_{i+1,i}).$$

Lemma 5.1 *There is an isomorphism of R -modules, natural in X ,*

$$H^i(AB^*(X)) \cong \ker \delta_i / \text{im } \delta_{i-1}.$$

Proof By Proposition 4.4, the universal coefficient spectral sequence

$$E_2^p = \text{Ext}_R^p(H_*^T(X_{i+1}, X_{i-1}), R) \Rightarrow H_T^*(X_{i+1}, X_{i-1})$$

collapses (since $E_2^p = 0$ unless $p = i$ or $i + 1$), and there is a short exact sequence

$$(5-3) \quad 0 \rightarrow \mathcal{E}^{i+1}(M_{i+1,i-1}) \rightarrow H_T^*(X_{i+1}, X_{i-1}) \rightarrow \mathcal{E}^i(M_{i+1,i-1}) \rightarrow 0$$

coming from the filtration of the spectral sequence.

Consider the following (possibly non-commuting) diagram:

$$\begin{array}{ccccccc} H_T^*(X_{i+1}, X_{i-1}) & \rightarrow & H_T^*(X_i, X_{i-1}) & \xrightarrow{d_i} & H_T^*(X_{i+1}, X_i) & \rightarrow & H_T^*(X_{i+1}, X_{i-1}) \\ & & \downarrow \phi_i & & \uparrow \psi_{i+1} & & \uparrow \\ 0 \rightarrow \mathcal{E}^i(M_{i+1,i-1}) & \longrightarrow & \mathcal{E}^i(M_{i,i-1}) & \xrightarrow{\delta_i} & \mathcal{E}^{i+1}(M_{i+1,i}) & \rightarrow & \mathcal{E}^{i+1}(M_{i+1,i-1}) \rightarrow 0 \end{array}$$

The rows are part of long exact sequences; the bottom one is based on the bottom row of (5-1) and uses again Proposition 4.4. The vertical maps come from (5-3), and ϕ_i and ψ_{i+1} are isomorphisms, once again by Proposition 4.4. The left square and the right square commute by naturality. Hence ϕ_i maps $\ker d_i$ isomorphically onto $\ker \delta_i$, and ψ_{i+1} maps $\text{im } \delta_i$ isomorphically onto $\text{im } d_i$.

The maps ϕ_i and ψ_i are induced by the filtration of $H_T^*(X_i, X_{i-1})$ coming from the universal coefficient spectral sequence. But since $\text{Ext}_R^j(H_T^*(X_i, X_{i-1}), R) = 0$ for $j \neq i$, the filtration of $H_T^*(X_i, X_{i-1})$ has only one non-trivial step, ie, it looks like

$$(5-4) \quad 0 = \dots = 0 = \mathcal{F}^{i+1} \subset \mathcal{F}^i = H_T^*(X_i, X_{i-1}) = \mathcal{F}^{i-1} = \dots = \mathcal{F}^0.$$

By the properties of spectral sequences the composition $\psi_i \phi_i$ is the inclusion $\mathcal{F}^i \hookrightarrow \mathcal{F}^{i-1}$, which in our case is the identity. So $\phi_i = \psi_i^{-1}$ for any i .

As a consequence, ϕ_i induces an isomorphism

$$\ker d_i / \text{im } d_{i-1} \rightarrow \ker \delta_i / \text{im } \delta_{i-1}. \quad \square$$

Proof of Corollary 4.7 Applying $\text{Ext}_R(-, R)$ to the diagram (5-1) leads to the commutative diagram:

$$\begin{array}{ccccc} \mathcal{E}^i(H_*^T(X_{i+1})) & \longrightarrow & \mathcal{E}^i(H_*^T(X_i)) & \longrightarrow & \mathcal{E}^{i+1}(M_{i+1,i}) \\ & & \uparrow & & \uparrow = \\ & & \mathcal{E}^i(M_{i,i-1}) & \xrightarrow{\delta_i} & \mathcal{E}^{i+1}(M_{i+1,i}) \end{array}$$

Together with the analogous square for $i - 1$ instead of i we can form the commutative diagram

$$\begin{array}{ccccccc} & & 0 & & & & \\ & & \uparrow & & & & \\ & & \mathcal{E}^{i-1}(H_*^T(X_{i-1})) & \xrightarrow{=} & \mathcal{E}^{i-1}(H_*^T(X_{i-1})) & & \\ & & \uparrow & & \downarrow & & \\ \mathcal{E}^{i-1}(M_{i-1,i-2}) & \xrightarrow{\delta_{i-1}} & \mathcal{E}^i(M_{i,i-1}) & \xrightarrow{\delta_i} & \mathcal{E}^{i+1}(M_{i+1,i}) & & \\ & & \downarrow p_i & & \uparrow & & \\ & & \mathcal{E}^i(H_*^T(X_i)) & \xrightarrow{=} & \mathcal{E}^i(H_*^T(X_i)) & & \\ & & \downarrow & & \uparrow & & \\ & & 0 & & \mathcal{E}^i(H_*^T(X_{i+1})) & & \\ & & & & \uparrow & & \\ & & & & 0 & & \end{array}$$

where all columns come from the long exact sequence for Ext , applied to some row of (5-1). We have used Proposition 4.4 to obtain the zero entries. As a consequence,

(5-5) $\ker \delta_i = p_i^{-1}(\mathcal{E}^i(H_*^T(X_{i+1}))),$

(5-6) $\text{im } \delta_{i-1} = \ker p_i.$

Hence

(5-7) $H^i(AB^*(X)) = \ker \delta_i / \text{im } \delta_{i-1} \cong \mathcal{E}^i(H_*^T(X_{i+1})) \cong \mathcal{E}^i(H_*^T(X)).$

The last isomorphism follows from Proposition 4.4 and the short sequence

(5-8) $0 = \mathcal{E}^i(H_*^T(X, X_{i+1})) \rightarrow \mathcal{E}^i(H_*^T(X)) \rightarrow \mathcal{E}^i(H_*^T(X_{i+1})) \rightarrow \mathcal{E}^{i+1}(H_*^T(X, X_{i+1})) = 0.$

This completes the proof. □
