HOMOGENIZATION OF NEUMANN BOUNDARY DATA WITH FULLY NONLINEAR OPERATOR

#### HOMOGENIZATION OF NEUMANN BOUNDARY DATA WITH FULLY NONLINEAR OPERATOR

SUNHI CHOI, INWON C. KIM AND KI-AHM LEE

In this paper we study periodic homogenization problems for solutions of fully nonlinear PDEs in half-spaces with oscillatory Neumann boundary data. We show the existence and uniqueness of the homogenized Neumann data for a given half-space. Moreover, we show that there exists a continuous extension of the homogenized slope as the normal of the half-space varies over "irrational" directions.

#### 1. Introduction

In this paper, we consider the averaging phenomena for solutions of uniformly elliptic nonlinear PDEs in half-spaces coupled with oscillatory Neumann boundary data. To be precise, let  $\mathcal{M}^{n-1}$  be the normed space of symmetric  $n \times n$  matrices and consider the function  $F(M) : \mathcal{M}^{n-1} \to \mathbb{R}$ , which satisfies:

(F1) F is uniformly elliptic, that is, there exist constants  $0 < \lambda < \Lambda$  such that

$$\lambda ||N|| < F(M) - F(M+N) < \Lambda ||N||$$
 for any  $N > 0$ ;

- (F2) (homogeneity) F(tM) = tF(M) for any  $M \in \mathcal{M}^{n-1}$  and t > 0. In particular, F(0) = 0.
- (F3) F(M) only depends on the eigenvalues of M.

The homogeneity condition (F2) can be relaxed (see condition (F4) of [Barles et al. 2008], for example). Typical examples of nonlinear operators that satisfy (F1)–(F3) are the Pucci extremal operators

$$\mathcal{P}^+(D^2u(x)) := \lambda \sum_{\mu_i < 0} \mu_i + \Lambda \sum_{\mu_i \geq 0} \mu_i, \quad \mathcal{P}^-(D^2u(x)) := \Lambda \sum_{\mu_i < 0} \mu_i + \lambda \sum_{\mu_i \geq 0} \mu_i,$$

where  $\mu_1, \ldots, \mu_n$  are eigenvalues of  $D^2u(x)$ .

Let  $\{e_1, \ldots, e_n\}$  be an orthonormal basis of  $\mathbb{R}^n$  and suppose  $g(x) : \mathbb{R}^n \to \mathbb{R}$  satisfies

- (a)  $g \in C^{\beta}(\mathbb{R}^n)$  for some  $0 < \beta \le 1$ ;
- (b)  $g(x + e_k) = g(x)$  for all  $x \in \mathbb{R}^n$  and k = 1, ..., n.

Next, for a given  $p \in \mathbb{R}^n$ , let  $\Pi_{\nu}(p)$  be a strip domain in  $\mathbb{R}^n$  with unit normal  $\nu$ , that is,

$$\Pi_{\nu}(p) = \{x : -1 \le (x - p) \cdot \nu \le 0\}, \text{ where } |\nu| = 1.$$
 (1)

With F, g and  $\Pi_{\nu}$  as given above, our goal is to describe the limiting behavior of  $u_{\varepsilon}$  as  $\varepsilon \to 0$ , where

Kim was partially supported by NSF grant DMS-0970072. Lee was partially supported by NRF grant MEST 2010-0001985. *MSC2010:* 35B27, 35J25, 35J60.

Keywords: homogenization, boundary layer, fully nonlinear elliptic PDE, viscosity solutions, Neumann boundary data.

 $u_{\varepsilon}$  satisfies

$$\begin{cases} F(D^2 u_{\varepsilon}) = 0 & \text{in } \Pi_{\nu}(p), \\ \nu \cdot D u_{\varepsilon} = g(x/\varepsilon) & \text{on } \Gamma_0 := \{(x-p) \cdot \nu = 0\}, \\ u = 1 & \text{on } \Gamma_I := \{(x-p) \cdot \nu = -1\}. \end{cases}$$

The fixed boundary data on  $\Gamma_I$  is introduced to avoid discussion of the compatibility condition on g and to ensure the existence of  $u^{\varepsilon}$ .

Homogenization of elliptic, divergence-form equations with oscillatory coefficients and conormal boundary data is a classical subject. Let  $\Omega$  be an open and bounded subset of  $\mathbb{R}^n$ . Consider  $u^{\varepsilon}: \bar{\Omega} \to \mathbb{R}$  solving

$$\nabla \cdot \left( A \left( \frac{x}{\varepsilon} \right) \nabla u_{\varepsilon} \right) = 0, \tag{2}$$

with the Neumann (conormal) condition

$$v \cdot \left( A \left( \frac{x}{\varepsilon} \right) \nabla u \right) (x) = g \left( \frac{x}{\varepsilon} \right), \quad x \in \partial \Omega.$$
 (3)

The problem (2)–(3) has been widely studied, and by now has been well understood; see [Bensoussan et al. 1978] for an overview. We first consider the case when  $\Omega$  is a half-space; thus, let

$$\Omega = \Sigma_{\nu} := \{x : (x - p) \cdot \nu \le 0\}.$$

We define the averaged Neumann data

$$\mu(\nu,\varepsilon) := \int_{(x-p)\cdot\nu=0, |x-p| \le 1} g\left(\frac{x}{\varepsilon}\right) dx. \tag{4}$$

Integrating by parts, one can show that  $u^{\varepsilon}$  locally uniformly converges to a continuous function  $u^{0}: \bar{\Omega} \to \mathbb{R}$  as  $\varepsilon \to 0$  if and only if  $\mu(\nu) := \lim_{\varepsilon \to 0} \mu(\nu, \varepsilon)$  exists, and that  $u^{0}$  solves the averaged equation

$$\begin{cases} -\nabla \cdot (A^0 \nabla u^0)(x) = 0 & \text{for } x \in \Omega, \\ \nu \cdot (A^0 \nabla u^0) = \mu(\nu) & \text{for } x \in \partial \Omega. \end{cases}$$

Therefore, different results hold depending on the choice of p and v:

- (a) If  $\nu$  is a "rational" vector one parallel to a vector in  $\mathbb{Z}^n$  then  $\mu(\nu)$  exists if p=0, and
  - $\mu(\nu)$  = the average of g(y) on the hyperplane  $\{x \cdot \nu = 0\}$ .
- (b) If  $\nu$  is a rational vector and  $p \neq 0$ , then there may be no limit of  $\mu(\nu, \varepsilon)$  and  $u^{\varepsilon}$  can have different subsequential limits.
- (c) If  $\nu$  is not a rational vector, then due to Weyl's equidistribution theorem (Lemma 2.5),  $\mu(\nu, \varepsilon)$  converges to

 $\mu(v) = \langle g \rangle := \int_{[0,1]^n} g(y) \, dy,$ 

independent of the choice of p. In particular, the homogenized slope  $\mu(\nu)$  is discontinuous at every rational direction  $\nu$ , but otherwise continuous.

From these results, the divergence form of the operator, and the fact that rational directions are of zero measure in  $\mathcal{G}^{n-1} := \{x \in \mathbb{R}^n : |x| = 1\}$ , the following results hold for the general domain  $\Omega$ : if  $\partial \Omega$  does not contain flat pieces whose normal vectors belong to  $\mathbb{R}\mathbb{Z}^n$ , then  $u^{\varepsilon}$  converges locally uniformly to the solution  $u^0$  of  $(\bar{P}_{\text{div}})$  with  $\mu(\nu)$  replaced by  $\langle g \rangle$ . We refer to [Bensoussan et al. 1978] for detailed analysis. Note that  $u^0$  is smooth up to the boundary, due to the fact that  $\langle g \rangle$  is continuous (constant in particular).

For nonlinear or nondivergence operators, or for linear operators with oscillatory nonlinear boundary data, little is known for the homogenization of the oscillating Neumann boundary data. Most available results concern half-space domains going through the origin with its normal pointing to a rational direction. Tanaka [1984] considered some model problems in half-spaces whose boundary is parallel to the axes of the periodicity, by purely probabilistic methods. Arisawa [2003] studied special cases of problems in oscillatory domains near half-spaces going through the origin, using viscosity solutions as well as stochastic control theory. Generalizing her results, Barles, Da Lio and Souganidis [Barles et al. 2008] studied the problem for operators with oscillating coefficients, in half-space domains whose boundary is parallel to the axes of periodicity, with a series of assumptions which guarantee the existence of an approximate corrector.

In this paper, we extend the results above to the setting of general half-spaces  $\Pi_{\nu}$ , defined in (1), where p is not necessarily zero and  $\nu$  ranges over all directions in  $\mathbb{R}^n$ . In particular, we show the continuity properties of the homogenized slope  $\mu(\nu)$  over the normal directions  $\nu$  (see Theorem 1.2(ii)), with the hope that such results will lead to better understanding of homogenization phenomena in domains with general geometry (work in progress). Note that, as observed in the linear case, homogenized slopes may not exist if  $\nu$  is parallel to a vector in  $\mathbb{Z}^n$  and if  $p \neq 0$ , and therefore the best result we can hope for is the existence of the continuous function  $\bar{\mu}(\nu)$ :  $S^{n-1} \to \mathbb{R}$  such that  $\bar{\mu}(\nu) = \mu(\nu)$  for  $\nu \in \mathcal{G}^{n-1} - \mathbb{R}\mathbb{Z}^n$ . This is precisely what we will show.

**Definition 1.1.** A direction  $v \in \mathcal{G}^{n-1}$  is called *rational* if  $v \in \mathbb{R}\mathbb{Z}^n$ , and *irrational* otherwise.

**Theorem 1.2** (Main Theorem). For a given  $p \in \mathbb{R}^n$ , let  $u_{\varepsilon}$  solve  $(P_{\varepsilon})$ .

(i) Let v be an irrational direction. Then there is a unique constant  $\mu(v) \in [\min g, \max g]$  such that  $u^{\varepsilon}$  locally uniformly converges to the solution of

$$\begin{cases} F(D^2u) = 0 & \text{in } \Pi_v, \\ v \cdot Du = \mu(v) & \text{on } \Gamma_0, \\ u = 1 & \text{on } \Gamma_I. \end{cases}$$

- (ii)  $\mu(v): (\mathcal{G}^{n-1} \mathbb{R}\mathbb{Z}^n) \to \mathbb{R}$  has a continuous extension  $\bar{\mu}(v): \mathcal{G}^{n-1} \to \mathbb{R}$ .
- (iii) For rational directions v, if  $\Gamma_0$  goes through the origin (that is if p=0), then the statement in (i) holds for v as well.
- (iv) (Error estimate). Let v be an irrational direction. Then for  $u^{\varepsilon}$  and u solving  $(P_{\varepsilon})$  and  $(\bar{P})$ , we have the following estimate: for any  $0 < \alpha < 1$ , there exists a constant  $C_{\alpha} > 0$  such that

$$|u^{\varepsilon} - u| \le C_{\alpha} \omega(\varepsilon)^{\alpha} \quad \text{in } \Pi_{\nu}. \tag{5}$$

Here  $\omega(\varepsilon)$  depends on the "discrepancy" associated to v as defined in (7).

**Remark 1.3.** Our method can be applied to the operators of the form  $F(D^2u, x) = f(x)$ , with F and f continuous in x, but we will restrict ourselves to the simple case discussed in  $(P_{\varepsilon})$  for clarity of exposition. On the other hand, our proof for the continuity of  $\mu(\nu)$  (Theorem 1.2(ii)) on page 965, cannot handle the case where the operator F depends on the oscillatory variable  $x/\varepsilon$  (see Remark 4.8).

#### 2. Preliminary results

Let  $\Omega$  be an open, bounded domain. Let  $\Gamma_I$  be a part of its boundary, and define  $\Gamma_0 := \partial \Omega - \Gamma_I$ . For a continuous function  $f(x, v): \mathbb{R}^n \times \mathcal{G}^{n-1} \to \mathbb{R}$ , let us recall the definition of viscosity solutions for the following problem:

$$\begin{cases} F(D^2u) = 0 & \text{in } \Omega, \\ v \cdot Du = f(x, v) & \text{on } \Gamma_0, \\ u = 1 & \text{on } \Gamma_I, \end{cases}$$

where  $v = v_x$  denotes the outward normal at  $x \in \partial \Omega$  with respect to  $\Omega$ .

The following definition is equivalent to the ones given in [Crandall et al. 1992]:

**Definition 2.1.** (a) An upper semicontinuous function  $u: \bar{\Omega} \to \mathbb{R}$  is a viscosity subsolution of  $(P)_f$  if

- (i)  $u \leq 1$  on  $\Gamma_I$ , and
- (ii) for a given domain  $\Sigma \subset \mathbb{R}^n$ , u cannot cross from below any  $C^2$  function  $\phi$  in  $\Sigma$  which satisfies

(ii) for a given domain 
$$\Sigma\subset\mathbb{R}$$
,  $u$  cannot cross from below any  $C$  -function  $\psi$  in  $\Sigma$  
$$\begin{cases} F(D^2\phi)>0 & \text{in }\Omega\cap\Sigma,\\ \nu\cdot D\phi>f(x,\nu) & \text{on }\Gamma_0\cap\Sigma,\\ \phi>u & \text{on }(\partial\Sigma\cup\Gamma_I)\cap\bar{\Sigma}. \end{cases}$$
 (b) A lower semicontinuous function  $u:\bar{\Omega}\to\mathbb{R}$  is a *viscosity supersolution* of  $(P)_f$  if:

- - (i)  $u \ge 1$  on  $\Gamma_I$ ;
  - (ii) for a given domain  $\Sigma \subset \mathbb{R}^n$ , u cannot cross from above any  $C^2$  function  $\varphi$  which satisfies

$$\begin{cases} F(D^2\phi) < 0 & \text{in } \Omega \cap \Sigma, \\ v \cdot D\phi < f(x, v) & \text{on } \Gamma_0 \cap \Sigma, \\ \phi < u & \text{on } (\partial \Sigma \cup \Gamma_I) \cap \bar{\Sigma}. \end{cases}$$

(c) u is a viscosity solution of  $(P)_f$  if u is both a viscosity sub- and supersolution of  $(P)_f$ .

Existence and uniqueness of viscosity solutions of  $(P)_f$  is based on the comparison principle we state below:

**Theorem 2.2** [Ishii and Lions 1990, Section V]. Suppose  $\Omega$ ,  $\Gamma_I$ ,  $\Gamma_0$ , F and v are as given above, and let  $f: \mathbb{R}^n \times \mathcal{S}^{n-1} \to \mathbb{R}$  be continuous. Let u and v respectively be a viscosity sub- and supersolution of  $(P)_f$ in a domain  $\Sigma \subset \mathbb{R}^n$ . If  $u \leq v$  on  $\partial \Sigma$ , then  $u \leq v$  in  $\Omega$ .

For details on the proof of this theorem as well as well-posedness of the problem  $(P)_f$ , we refer to [Crandall et al. 1992; Ishii 1991; Ishii and Lions 1990].

Next we state some regularity results that will be used in the paper.

**Theorem 2.3** [Caffarelli and Cabré 1995, Chapter 8, modified for our setting]. Let u be a viscosity solution of  $F(D^2u) = 0$  in a domain  $\Omega$ . For any  $0 < \alpha < 1$  and for any compact subset  $\Omega'$  of  $\Omega$ , we have

$$||u||_{C^{\alpha}(\Omega')} \leq Cd^{-\alpha}||u||_{L^{\infty}(\Omega)},$$

where C > 0 depends on  $n, \lambda, \Lambda$  and  $d = d(\Omega', \partial\Omega)$ .

Theorem 2.4 [Milakis and Silvestre 2006, Theorems 8.1 and 8.2]. Let

$$B_r^+ := \{|x| < r\} \cap \{x \cdot e_n \ge 0\}$$
 and  $\Gamma := \{x \cdot e_n = 0\} \cap B_1$ .

Let u be a viscosity solution of

$$\begin{cases} F(D^2u) = 0 & \text{in } B_1^+, \\ v \cdot Du = g & \text{in } \Gamma. \end{cases}$$

(a) If g is bounded, then u is in  $C^{\alpha}(\overline{B_{1/2}^+})$  for some  $\alpha = \alpha(n, \lambda, \Lambda)$ , and we have the estimate

$$||u||_{C^{\alpha}(\overline{B_{1/2}^{+}})} \le C(||u||_{L^{\infty}(\overline{B_{1}^{+}})} + \max ||g||).$$

(b) Suppose  $g \in C^{\beta}(\mathbb{R}^n)$ , where  $0 < \beta \le 1$ . Then u is in  $C^{1,\gamma}(\overline{B_{1/2}^+})$ , where  $\gamma = \min(\alpha_0, \beta)$  and  $\alpha_0 = \alpha_0(n, \lambda, \Lambda)$ . Moreover, we have the estimate

$$\|u\|_{C^{1,\alpha}(\overline{B_{1/2}^+})} \le C(\|u\|_{L^{\infty}(\overline{B_1^+})} + \|g\|_{C^{\beta}}).$$

In (a) and (b), the positive constant C depends only on n,  $\lambda$ ,  $\Lambda$  and  $\alpha$ .

Let us next discuss the averaging property of the sequence  $(nx)_n \mod 1$ , where x is an irrational number, and its applications to dimensions greater than 1, which will prove useful in our analysis in Section 3. Since we obtain estimates on the convergence rate of solutions for  $(P_{\varepsilon})$  in our result, we are particularly interested in the estimates on the rate of convergence of the sequence  $(nx)_n$  to the uniform distribution (Definition 2.6). We begin by recalling the notion of equidistribution.

• A bounded sequence  $(x_1, x_2, x_3...)$  of real numbers is said to be *equidistributed* on an interval [a, b] if for any  $[c, d] \subset [a, b]$ , we have

$$\lim_{n\to\infty} \frac{\left| \{x_1,\ldots,x_n\} \cap [c,d] \right|}{n} = \frac{d-c}{b-a}.$$

Here  $|\{x_1, \ldots, x_n\} \cap [c, d]|$  denotes the number of elements.

• The sequence  $(x_1, x_2, x_3, ...)$  is said to be equidistributed modulo 1 if  $(x_1 - [x_1], x_2 - [x_2], ...)$  is equidistributed in the interval [0, 1].

**Lemma 2.5** [Weyl 1910, Weyl's equidistribution theorem]. If a is an irrational number, (a, 2a, 3a, ...) is equidistributed modulo 1.

To discuss quantitative versions of Lemma 2.5, we introduce the notion of discrepancy.

**Definition 2.6** [Kuipers and Niederreiter 1974]. Let  $(x_k)$ , k = 1, 2, ... be a sequence in  $\mathbb{R}$ . For a subset  $E \subset [0, 1]$ , let A(E; N) denote the number of points  $\{x_n\}$ ,  $1 \le n \le N$ , that lie in E.

(a) The sequence  $(x_n)$ , n = 1, 2, ... is said to be uniformly distributed mode 1 in  $\mathbb{R}$  if

$$\lim_{N \to \infty} \frac{A(E; N)}{N} = \mu(E)$$

for all E = [a, b). Here  $\mu$  denotes the Lebesgue measure.

(b) For  $x \in [0, 1]$ , we define the discrepancy

$$D_N(x) := \sup_{E=[a,b]} \left| \frac{A(E;N)}{N} - \mu(E) \right|,$$

where A(E; N) is defined with the sequence  $(kx), k \in \mathbb{N}$ , modulo 1.

It easily follows from Lemma 2.5 that the sequence  $(x_k) = (kx)_{k \in \mathbb{N}}$  is uniformly distributed modulo 1 for any irrational number  $x \in \mathbb{R}$ . In particular,  $D_N(x)$  converges to zero as  $N \to \infty$ .

Next, let  $\mathcal{G}^{n-1} = \{ \nu \in \mathbb{R}^n : |\nu| = 1 \}$ . For a direction  $\nu = (\nu_1, \dots, \nu_n) \in \mathcal{G}^{n-1}$ , let  $\nu_i$  be the component with the biggest size, that is,

$$|v_i| = \max\{|v_j| : 1 \le j \le n\}.$$

(If there are multiple components, then we choose the one with largest index.)

Let  $H_{\nu}$  be the hyperplane in  $\mathbb{R}^n$  which passes through 0 and is normal to  $\nu$ :

$$H_{\nu} = \{ x \in \mathbb{R}^n : x \cdot \nu = 0 \}.$$

Since  $v_i \neq 0$ , there exists m(v) such that

$$(1, \dots, 1, m(\nu), 1, \dots, 1) \cdot \nu = 0,$$
 (6)

where m(v) is the *i*-th component of  $(1, \ldots, 1, m(v), 1, \ldots, 1)$ . Then we define

$$\omega_{\nu}(\varepsilon) := D_N(m(\nu)), \quad \text{where } N = \varepsilon^{-9/10}.$$
 (7)

Note that, if m(v) is irrational, then  $\omega_v(\varepsilon) \to 0$  as  $\varepsilon \to 0$ .

Now we are ready to state our quantitative estimate on the averaging properties of the vector sequence  $(n\nu)$  with an irrational direction  $\nu$ , which will be used in the rest of the paper. Recall that for  $\nu \in \mathcal{G}^{n-1}$ ,  $\Pi_{\nu}(p) = \{x : -1 \le (x-p) \cdot \nu \le 0\}$ . Write  $\Gamma_0 = \{x : (x-p) \cdot \nu = 0\}$  and define

$$H_{\nu} = \{x : x \cdot \nu = 0\}.$$

**Lemma 2.7.** For  $v \in \mathbb{R}^n$  and  $x_0 \in \Pi_v$ , let  $H(x_0) := H_v + x_0$ . Let  $0 < \varepsilon < \operatorname{dist}(x_0, \Gamma_0)$ .

(i) Suppose that v is a rational direction. Then for any  $x \in H(x_0)$ , there is  $y \in H(x_0)$  such that

$$|x - y| \le M_{\nu} \varepsilon, \quad y - x_0 \in \varepsilon \mathbb{Z}^n,$$

where  $M_{\nu} > 0$  is a constant depending on  $\nu$ .

(ii) Suppose that v is an irrational direction, and let  $\omega_v : [0, 1) \to \mathbb{R}^+$  be defined as in (7). Then there exists a dimensional constant M > 0 such that the following is true: for any  $x \in H(x_0)$ , there is  $y \in \mathbb{R}^n$  such that

$$|x - y| \le M\varepsilon^{1/10}, \quad y - x_0 \in \varepsilon \mathbb{Z}^n$$

and

$$\operatorname{dist}(y, H(x_0)) < \varepsilon \omega_y(\varepsilon), \tag{8}$$

where  $\omega_{\nu}$  is as given in (7).

(iii) If v is an irrational direction, then for any  $z \in \mathbb{R}^n$  and  $\delta > 0$ , there is  $w \in H(x_0)$  such that

$$|z-w| \leq \delta \mod \varepsilon \mathbb{Z}^n$$
.

*Proof.* The proof of (i) is immediate from the fact that for any rational direction  $\nu$ , there exists an integer M > 0 depending on  $\nu$  such that  $M\nu \in \mathbb{Z}^n$ .

Next, we prove (ii). Let  $\nu$  be an irrational direction in  $\mathbb{R}^n$ . Without loss of generality, we may assume

$$|\nu_n| = \max\{|\nu_j| : 1 \le j \le n\}.$$

Let x be any point on  $H(x_0)$ : after a translation, we may assume that x = 0. Choose m such that

$$\varepsilon(1, 1, \ldots, 1, m) \in H(x_0).$$

Note that  $M = |m| \le n^2$ . Also note that m is irrational since  $\nu$  is an irrational direction. Since  $H(x_0)$  contains x = 0, we have

$$k\varepsilon(1,1,\ldots,1,m)\in H(x_0)$$
 for any integer k.

Consider the sequence (km),  $k \in \mathbb{N}$ . From the definition of  $\omega_{\nu}(\varepsilon)$  and the discrepancy function  $D_N(m)$ , it follows that any interval  $[a, b] \subset [0, 1]$  of length  $\omega_{\nu}(\varepsilon)$  contains at least one point  $km \pmod 1$ , for some  $k < N = \varepsilon^{-9/10}$ .

Hence for any  $z = (0, 0, ..., 0, x_n) \in [0, \varepsilon]^n$ , there exists

$$w = k\varepsilon(1, 1, ..., 1, m) \in H(x_0), \quad 0 \le k \le \varepsilon^{-9/10}$$

such that

$$|z-w| \le \varepsilon \omega_{\nu}(\varepsilon) \mod \varepsilon \mathbb{Z}^n$$
.

Similarly, for any  $z \in [0, \varepsilon]^n$ , there exists  $w \in H(x_0) \cap (k\varepsilon(1, 1, ..., 1, m) + [0, \varepsilon]^n)$  such that

$$|z - w| \le \varepsilon \omega_{\nu}(\varepsilon) \mod \varepsilon \mathbb{Z}^n, \quad 0 \le k \le \varepsilon^{-9/10}.$$
 (9)

We continue with the proof of (ii). Recall that the coordinates are shifted so that x = 0. Thus it suffices to find  $y \in \mathbb{R}^n$  such that

$$|x - y| = |y| \le M\varepsilon^{1/10}$$
,  $|y - x_0| = 0 \mod \varepsilon \mathbb{Z}^n$ 

and

$$\operatorname{dist}(y, H(x_0)) < \varepsilon \omega_{\nu}(\varepsilon)$$
.

By (9), there exists  $w \in H(x_0)$  such that

$$|x - w| = |w| \le Mk\varepsilon \le M\varepsilon^{1/10} \tag{10}$$

and

$$|x_0 - w| \le \varepsilon \omega_{\nu}(\varepsilon) \mod \varepsilon \mathbb{Z}^n.$$
 (11)

Given w satisfying (11), we can take  $y \in \mathbb{R}^n$  such that

$$|x_0 - y| = 0 \mod \varepsilon \mathbb{Z}^n, \quad |y - w| \le \varepsilon \omega_{\nu}(\varepsilon).$$

Then, by (10),

$$|y| \le |y - w| + |w| \le M\varepsilon^{1/10} + \varepsilon\omega_{\nu}(\varepsilon) \le M\varepsilon^{1/10}$$

Also, since w is contained in  $H(x_0)$ , we have  $\operatorname{dist}(y, H(x_0)) \leq |y - w| \leq \varepsilon \omega_{\nu}(\varepsilon)$ , proving (ii). Finally, (iii) is a direct consequence of (9).

#### 3. In the strip domain

Fix  $p \in \mathbb{R}^n$  and  $\nu \in \mathcal{G}^{n-1}$  such that  $p \cdot \nu \neq 0$ . Let

$$\Pi = \Pi_{\nu} = \{ x \in \mathbb{R}^n : -1 \le (x - p) \cdot \nu \le 0 \}.$$

We consider a bounded viscosity solution  $u_{\varepsilon}$  of

$$\begin{cases} F(D^2 u_{\varepsilon}) = 0 & \text{in } \Pi, \\ \frac{\partial u_{\varepsilon}}{\partial v} = g\left(\frac{x}{\varepsilon}\right) & \text{on } \Gamma_0 := \{x : (x-p) \cdot v = 0\}, \\ u_{\varepsilon} = 1 & \text{on } \Gamma_I := \{x : (x-p) \cdot v = -1\}. \end{cases}$$

Below we prove the existence and uniqueness of  $u_{\varepsilon}$ .

**Lemma 3.1.** Let  $f(x) : \mathbb{R}^n \to \mathbb{R}$  be continuous and bounded. Let  $\Pi$  be as given above and define  $B_R(p) := \{|x - p| \le R\}$ . Suppose  $w_1$  and  $w_2$  solve, in the viscosity sense,

- (a)  $F(D^2w_1) = 0$  and  $F(D^2w_2) = 0$  in  $\Sigma_R := \Pi \cap B_R(p)$ ;
- (b)  $\partial w_1/\partial v = f(x) = \partial w_2/\partial v$  on  $\Gamma_0$ ;
- (c)  $w_1 = w_2 \text{ on } \Gamma_I$ ;
- (d)  $w_1 = -M$ ,  $w_2 = M$  on  $\Pi \cap \partial B_R(p)$ .

Then, for R > 2 and  $C = \frac{n\Lambda}{\lambda}$ , we have

$$w_1 \le w_2 \le w_1 + \frac{3CM}{R^2}$$
 in  $\Pi \cap B_1(p)$ .

*Proof.* Without loss of generality, let us set  $\nu = e_n$  and p = 0. The first inequality,  $w_1 \le w_2$ , directly follows from Theorem 2.2. To show the second inequality, consider  $\tilde{\omega} := w_1 + M(h_1 + h_2)$ , where

$$h_1 = \frac{1}{R^2} ((x_1)^2 + \dots + (x_n)^2)$$
 and  $h_2 = \frac{C}{R^2} (1 - (x_n)^2)$ ,

with  $C = \frac{n\Lambda}{\lambda}$ . We claim  $w_2 \leq \tilde{\omega}$ . To see this, note that

$$\begin{split} F(D^2\tilde{\omega}) &= F(D^2w_1 + D^2h_1 + D^2h_2) \\ &\geq F(D^2w_1) + \frac{2}{R^2}(C\lambda - n\Lambda) \geq F(D^2w_1) \text{ in } \Sigma_R. \end{split}$$

On the boundary of  $\Sigma_R$ ,  $\tilde{\omega}$  satisfies

$$\partial_{x_n}\tilde{\omega} = \partial_{x_n}\omega_1 = \partial_{x_n}\omega_2$$
 on  $\Sigma_R \cap \{x_n = 0\}$ 

and

$$w_2 \leq \tilde{\omega}$$
 on  $\Gamma_I \cap B_R(0)$  and on  $\partial B_R(0) \cap \Pi$ .

It follows from Theorem 2.2 that  $w_2 \leq \tilde{\omega}$  in  $\Sigma_R$ , and we are done.

**Lemma 3.2.** There exists a unique bounded solution u of  $(P_{\varepsilon})$ .

*Proof.* 1. Let  $\Sigma_R$  be as given in Lemma 3.1, and consider the viscosity solution  $\omega_R(x)$  of  $(P_{\varepsilon})$  in  $\Sigma_R$  with the lateral boundary data M=1 on  $\partial B_R(p) \cap \Pi$ . The existence and uniqueness of the viscosity solution  $\omega_R$  is shown, for example, in [Crandall et al. 1992; Ishii 1991; Ishii and Lions 1990].

By the maximum principle,  $\omega_R \le 1 + \max(g)$  in  $\Sigma_R$ . Due to Theorem 2.4 and the Arzelà–Ascoli Theorem,  $\omega_R$  locally uniformly converges to a continuous function  $u_{\varepsilon}(x)$ . Then by the stability property of viscosity solutions, it follows that  $u_{\varepsilon}(x)$  is a viscosity solution of  $(P_{\varepsilon})$ .

2. To show uniqueness, suppose  $u_1$  and  $u_2$  are both viscosity solutions of  $(P_{\varepsilon})$  with  $|u_1|, |u_2| \leq M$ . Then Lemma 3.1 yields that, for any point  $q \in \Gamma_0$  and any R > 2,

$$|u_1-u_2|\leq O\left(\frac{1}{R^2}\right)$$
 in  $B_1(q)\cap\Pi$ .

Hence  $u_1 = u_2$ .

The following is immediate from Theorem 2.2 and the construction of  $u_{\varepsilon}$  in the above lemma.

**Corollary 3.3.** Suppose u and v are bounded and continuous in  $\bar{\Pi}_{\nu}(p)$ , and solve

- a)  $F(D^2u) \le 0 \le F(D^2v)$  in  $\Pi_v(p)$ ;
- b)  $u \leq v \text{ on } \Gamma_I$ ;
- c)  $\partial u/\partial v \leq f(x) \leq \partial v/\partial v$  on  $\Gamma_0$ ;

where  $f(x): \mathbb{R}^n \to \mathbb{R}$  is continuous. Then  $u \leq v$  in  $\Pi_{\nu}(p)$ .

In the rest of this section, we will repeatedly use the fact that linear profiles as well as constants solve  $F(D^2u) = 0$ .

**Lemma 3.4.** Let  $\Pi_{\nu}(p)$  be as given in  $(P_{\varepsilon})$  and let  $0 < \varepsilon < 1$ . Suppose that  $w_1$  and  $w_2$  are bounded and solve, in the viscosity sense,

$$\begin{cases} F(D^2w_i) = 0 & \text{in } \Pi_{\nu}(p), \\ |w_1 - w_2| \le \varepsilon & \text{on } \Gamma_I, \\ \frac{\partial w_1}{\partial \nu} - \frac{\partial w_2}{\partial \nu} = A & \text{on } \Gamma_0. \end{cases}$$

Then there exists a positive constant C = C(A) such that

$$|w_1 - w_2| \ge C - \varepsilon$$
 in  $\Pi_{\nu}(p) \cap B_{1/2}(p)$ .

*Proof.* Let  $\tilde{w} := w_2 + h$ , where  $h(x) = A(x - p) \cdot v + A - \varepsilon$ . Then  $\partial \tilde{\omega} / \partial v = \partial \omega_1 / \partial v$  on  $\Gamma_0$ . Also,  $\tilde{\omega} \le w_1$  on  $\Gamma_I$ . Therefore, Corollary 3.3 yields that  $w_2 + h \le w_1$ . Since  $h \ge A/2 - \varepsilon$  in  $B_{1/2}(p)$ , we are done.  $\square$ 

**Lemma 3.5.** Let  $\tilde{\Pi} = \Pi + av$  for some  $0 \le a \le A\varepsilon$ , where 0 < A < 1. Suppose  $u_{\varepsilon}$  and  $\tilde{u}_{\varepsilon}$  are bounded, and solve  $(P_{\varepsilon})$  respectively in the domains  $\Pi$  and  $\tilde{\Pi}$ . Then we have

$$|u_{\varepsilon} - \tilde{u}_{\varepsilon}| < C(A^{\beta} + \varepsilon^{\alpha})$$
 in  $\Pi \cap \tilde{\Pi}$ ,

where  $\alpha$  is as given in Theorem 2.4 and  $\beta$  is the Hölder exponent of g.

*Proof.* 1. Let  $v_{\varepsilon}(x) = \tilde{u}_{\varepsilon}(x + av)$ , so that  $v_{\varepsilon}$  and  $u_{\varepsilon}$  are defined in the same domain  $\Pi$ . Since  $g(x) \in C^{\beta}(\mathbb{R}^{n})$ ,  $|\partial v_{\varepsilon}/\partial v - \partial u_{\varepsilon}/\partial v| \leq A^{\beta}$  on  $\Gamma_{0}$ .

2. On  $\Gamma_I$ ,  $u_{\varepsilon} = v_{\varepsilon} = 1$ . Hence one can compare  $u_{\varepsilon} \pm A^{\beta}(1 + (x - p) \cdot v)$  with  $v_{\varepsilon}$  and apply Theorem 2.2 to obtain

$$|u_{\varepsilon}-v_{\varepsilon}|\leq A^{\beta}$$
 in  $\Pi$ .

Due to the Hölder continuity of  $u^{\varepsilon}$  given by Theorem 2.4,  $|v_{\varepsilon} - \tilde{u}_{\varepsilon}| \leq C \varepsilon^{\alpha}$  in  $\Pi \cap \tilde{\Pi}$ . This finishes the proof.

The next lemma follows from Theorem 2.4(b).

**Lemma 3.6.** Let  $v_j$  be a bounded solution of  $(P_{\varepsilon})$  with a constant Neumann condition  $g(x) = \mu_j$ . If  $\mu_i \to \mu$ , then  $v_j$  converges to v such that  $\partial v/\partial v = \mu$  on  $\Gamma_0$ .

#### 4. Proof of the Main Theorem

We will prove first parts (i), (iii) and (iv) of Theorem 1.2; the proof of part (ii) starts on page 965. Recall that

$$\Gamma_0 = \{x : (x - p) \cdot v = 0\}, \quad \Gamma_I = \{x : (x - p) \cdot v = -1\}.$$

Due to the uniform Hölder regularity of  $\{u_{\varepsilon}\}$  (Theorem 2.4(a)), along subsequences  $u_{\varepsilon_j} \to u$  in  $\bar{\Pi}_{\nu}$ . Note that there could be different limits along different subsequences  $(\varepsilon_j)$ . Below, we will show that if  $\nu$  is an irrational direction, all subsequential limits of  $(u_{\varepsilon})$  coincide.

Suppose

$$0 \in \Pi_{\nu} = \{-1 < (x - p) \cdot \nu < 0\}.$$

Let us choose a convergent subsequence and rename it  $(u_j)$ . For each j, there exists a constant  $\mu_j$  and a function  $v_j$  in  $\Pi_v(p)$  such that

$$\begin{cases} F(D^2v_j) = 0 & \text{in } \Pi_v(p), \\ \frac{\partial v_j}{\partial v} = \mu_j & \text{on } \Gamma_0, \\ v_j = u_j = 1 & \text{on } \Gamma_I, \\ v_j = u_j & \text{at } x = 0. \end{cases}$$

**Lemma 4.1.** We have  $\mu_j \to \mu$  for some  $\mu$  as  $j \to \infty$ . (The limit may depend on the subsequence chosen.) *Proof.* Suppose not; then there is a constant A > 0 such that for any N > 0,  $|\mu_m - \mu_n| \ge A$  for some m, n > N. Then, by Lemma 3.4,

$$|v_m(0) - v_n(0)| \ge C_A$$
.

This contradicts the fact that  $v_j(0) = u_j(0)$ , since  $u_j(0) \to u(0)$  as  $j \to \infty$ .

The next lemma states that  $u_{\varepsilon}$  looks like a linear profile with respect to the direction  $\nu$  as  $\varepsilon \to 0$ .

**Lemma 4.2.** Away from the Neumann boundary  $\Gamma_0$ ,  $u_{\varepsilon}$  is almost a constant on hyperplanes parallel to  $\Gamma_0$ . More precisely, let  $x_0 \in \Pi_{\nu}(p)$  with  $\operatorname{dist}(x_0, \Gamma_0) > \varepsilon^{1/20}$ , and let  $0 < \alpha < 1$ . Then:

(i) If v is a rational direction, there exists a constant C > 0 depending on v,  $\alpha$  and n, such that for any  $x \in H(x_0) := \{(x - x_0) \cdot v = 0\}$ ,

$$|u_{\varepsilon}(x) - u_{\varepsilon}(x_0)| \le C\varepsilon^{\alpha/2}. \tag{12}$$

(ii) If v is any irrational direction, there exists a constant C > 0 depending on  $\alpha$  and n, such that for any  $x \in H(x_0)$ ,

$$|u_{\varepsilon}(x) - u_{\varepsilon}(x_0)| \le C\varepsilon^{\alpha/20} + C\omega_{\nu}(\varepsilon)^{\beta},\tag{13}$$

where  $\omega_{\nu}:[0,1)\to[0,\infty)$  is a mode of continuity given as in (ii) of Lemma 2.7.

*Proof.* First, let  $\nu$  be a rational direction. Lemma 2.7 implies that for any  $x \in H(x_0)$ , there is  $y \in H(x_0)$  such that  $|x - y| \le M_{\nu} \varepsilon$  and  $u_{\varepsilon}(y) = u_{\varepsilon}(x_0)$ . Then by Theorem 2.3,

$$|u_{\varepsilon}(x_0) - u_{\varepsilon}(x)| \le C\varepsilon^{-\alpha/20} (M_{\nu}\varepsilon)^{\alpha} \le C\varepsilon^{\alpha/2}.$$

Next, we assume that  $\nu$  is an irrational direction and  $x \in H(x_0)$ . By (ii) of Lemma 2.7, there exists  $y \in \mathbb{R}^n$  such that  $|x - y| \le M\varepsilon^{1/10}$ ,  $y - x_0 \in \varepsilon \mathbb{Z}^n$  and

$$\operatorname{dist}(y, H(x_0)) < \varepsilon \omega(\varepsilon). \tag{14}$$

Then we obtain

$$|u_{\varepsilon}(x_{0}) - u_{\varepsilon}(x)| \leq |u_{\varepsilon}(x_{0}) - u_{\varepsilon}(y)| + |u_{\varepsilon}(y) - u_{\varepsilon}(x)|$$

$$\leq C(\omega(\varepsilon)^{\beta} + \varepsilon^{\alpha}) + |u_{\varepsilon}(y) - u_{\varepsilon}(x)|$$

$$\leq C\omega(\varepsilon)^{\beta} + C\varepsilon^{-\alpha/20} (M\varepsilon^{1/10})^{\alpha}$$

$$\leq C\omega(\varepsilon)^{\beta} + C\varepsilon^{\alpha/20}, \tag{15}$$

where the second inequality follows from Lemma 3.5 with (14), and the third inequality follows from Theorem 2.3.  $\Box$ 

By Lemma 4.2 and by the comparison principle (Theorem 2.2), we obtain the following estimate: for  $x \in \Pi$ ,

$$|u_{\varepsilon}(x) - v_{\varepsilon}(x)| \le \Lambda(\varepsilon), \tag{16}$$

where

$$\Lambda(\varepsilon) = \begin{cases} C \varepsilon^{\alpha/2} & \text{if } \nu \text{ is a rational direction,} \\ C \varepsilon^{\alpha/20} + C \omega_{\nu}(\varepsilon)^{\beta} & \text{if } \nu \text{ is any irrational direction.} \end{cases}$$

**Lemma 4.3.**  $\lim v_i = \lim u_i$ , and hence  $\partial u/\partial v = \mu$  on  $\Gamma_0$ .

*Proof.* Observe that  $v_j$  solves  $(P_{\varepsilon_j})$  with  $g = \mu_j$ : note that  $v_j$  is then a linear profile, that is,  $v_j(x) = \mu_j((x-p) \cdot v + 1) + 1$ . Let  $x_0$  be a point between  $\Gamma_0$  and H(0). Then by Lemma 4.2, applied to  $u_j$  and  $v_j$ ,

$$\left| (u_j(x) - v_j(x)) - (u_j(x_0) - v_j(x_0)) \right| \le \Lambda(\varepsilon_j), \tag{17}$$

for all  $x \in H(x_0)$ , if j is sufficiently large. Suppose now that

$$u_j(x_0) - v_j(x_0) > c > 0$$
, for sufficiently large j.

Then due to (17),  $u_j - v_j \ge c/2$  on  $H(x_0)$  if j is sufficiently large. Note that  $u_j$  can be constructed as the locally uniform limit of  $u_{j,R}$ , where  $u_{j,R}$  solves

$$F(D^2u_{j,R}) = 0$$
 in  $B_R(x_0) \cap \Pi$ ,  $u_{j,R} = v_j$  on  $\partial B_R(x_0) \cap \Pi$ ,

with

$$u_{j,R} = 1$$
 on  $\Gamma_I$ ,  $\frac{\partial}{\partial \nu} u_{j,R}(x) = g\left(\frac{x}{\varepsilon_i}\right)$  on  $\Gamma_0$ .

Comparing  $u_{j,R}$  and  $v_j + c((x - x_0) \cdot v + 1)$  on the domain

$$B_R(x_0) \cap \{x : -1 \le (x - p) \cdot \nu \le (x - x_0) \cdot \nu \}$$

for sufficiently large R then yields that  $u_{j,R}(0) \ge v_j(0) + c_0$  for all sufficiently large R, which would contradict the fact that  $v_j(0) = u_j(0)$ . Similarly, the case  $\liminf_j (u_j(x_0) - v_j(x_0)) < 0$  can be excluded, and it follows that

$$|u_i(x_0) - v_i(x_0)| \to 0$$
 as  $i \to \infty$ .

Hence we get  $v_j \to u$  in each compact subset of  $\Pi$ . By Lemmas 4.1 and 3.6, the limit u = v of  $v_j$  satisfies  $\partial u/\partial v = \mu$  on  $\Gamma_0$ .

**Lemma 4.4.** If v is an irrational direction,  $\partial u/\partial v = \mu_v$  for a constant  $\mu_v$  which depends on v, not on the subsequence  $\varepsilon_i$ .

*Proof.* 1. Let  $0 < \eta < \varepsilon$  be sufficiently small. Let

$$w_{\varepsilon}(x) = \frac{u_{\varepsilon}(\varepsilon x)}{\varepsilon}, \quad w_{\eta}(x) = \frac{u_{\eta}(\eta x)}{\eta},$$

and denote by  $\Gamma_1$  and  $\Gamma_2$  the Neumann boundary of  $w_{\varepsilon}$  and  $w_{\eta}$ , respectively. By (iii) of Lemma 2.7, for the point  $p \in \mathbb{R}^n$ , there exist  $q_1 \in \Gamma_1$  and  $q_2 \in \Gamma_2$  such that

$$|p-q_1| \le \eta \mod \mathbb{Z}^n$$
 and  $|p-q_2| \le \eta \mod \mathbb{Z}^n$ .

Hence after translations by  $p-q_1$  and  $p-q_2$ , we may suppose that  $w_{\varepsilon}(x)$  and  $w_{\eta}(x)$  are defined, respectively, on the extended strips

$$\Omega_{\varepsilon} := \left\{ x : -\frac{1}{\varepsilon} \le (x - p) \cdot \nu \le 0 \right\} \quad \text{and} \quad \Omega_{\eta} := \left\{ x : -\frac{1}{\eta} \le (x - p) \cdot \nu \le 0 \right\}.$$

Here,  $w_{\varepsilon} = 1/\varepsilon$  on  $\{(x-p) \cdot v = -1/\varepsilon\}$  and  $w_{\eta} = 1/\eta$  on  $\{(x-p) \cdot v = -1/\eta\}$ . Moreover, on  $\Gamma_0 := \{(x-p) \cdot v = 0\}$ , we have

$$\frac{\partial w_{\varepsilon}}{\partial \nu} = g_1(x) := g(x - z_1)$$
 and  $\frac{\partial w_{\eta}}{\partial \nu} = g_2(x) := g(x - z_2),$ 

where  $|z_1|$ ,  $|z_2| \le \eta$ . Observe that since g has Hölder exponent  $0 < \beta \le 1$ , we have  $|g_1 - g_2| \le \eta^{\beta}$ .

Let  $v_{\varepsilon}$  be a solution of the problem  $(P_{\varepsilon})$  with constant Neumann data  $\partial v_{\varepsilon}/\partial v = \mu_{\varepsilon}$  on  $\Gamma_0$  such that  $v_{\varepsilon}$  coincides with  $u_{\varepsilon}$  at x = 0 and on  $\Gamma_I$ . By (16),

$$\left| w_{\varepsilon}(x) - \frac{v_{\varepsilon}(\varepsilon x)}{\varepsilon} \right| \le \frac{C \varepsilon^{\alpha/20} + C \omega(\varepsilon)^{\beta}}{\varepsilon}. \tag{18}$$

Note that  $v_{\varepsilon}$  is a linear profile: indeed,

$$\frac{v_{\varepsilon}(\varepsilon x)}{\varepsilon} = \mu_{\varepsilon} \left( (x - p) \cdot v + \frac{1}{\varepsilon} \right) + \frac{1}{\varepsilon}.$$

From (18) and the comparison principle, it follows that, with  $\Lambda(\varepsilon) = C\varepsilon^{\alpha/20} + C\omega(\varepsilon)^{\beta}$ ,

$$\left(\mu_{\varepsilon} - \Lambda(\varepsilon)\right) \left((x - p) \cdot \nu + \frac{1}{\varepsilon}\right) \le w_{\varepsilon}(x) - \frac{1}{\varepsilon} \le \left(\mu_{\varepsilon} + \Lambda(\varepsilon)\right) \left((x - p) \cdot \nu + \frac{1}{\varepsilon}\right),\tag{19}$$

2. (19) means that the slope of  $w_{\varepsilon}$  in the direction of  $\nu$  (that is,  $\nu \cdot Dw_{\varepsilon}$ ) is between  $\mu_{\varepsilon} + \Lambda(\varepsilon)$  and  $\mu_{\varepsilon} - \Lambda(\varepsilon)$  on  $\{x : (x - p) \cdot \nu = -1/\varepsilon\}$ . Now let us consider linear profiles

$$l_1(x) = a_1(x - p) \cdot v + b_1$$
 and  $l_2(x) = a_2(x - p) \cdot v + b_2$ ,

whose respective slopes are  $a_1 = \mu_{\varepsilon} + \Lambda(\varepsilon)$  and  $a_2 = \mu_{\varepsilon} - \Lambda(\varepsilon)$ . Here  $b_1$  and  $b_2$  are chosen such that

$$l_1 = l_2 = \omega_{\eta}(x)$$
 on  $\left\{ x : (x - p) \cdot \nu = -\frac{1}{\eta} \right\}$ .

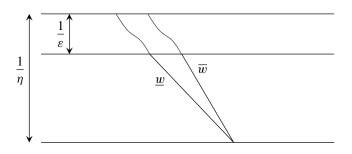

3. Now we define

$$\overline{w}(x) := \begin{cases} l_1(x) & \text{in } \left\{ -1/\eta \le (x-p) \cdot \nu \le -1/\varepsilon \right\}, \\ w_{\varepsilon}(x) + c_1 & \text{in } \left\{ -1/\varepsilon \le (x-p) \cdot \nu \le 0 \right\} \end{cases}$$

and

$$\underline{w}(x) := \begin{cases} l_2(x) & \text{in } \{-1/\eta \le (x-p) \cdot \nu \le -1/\epsilon\}, \\ w_{\varepsilon}(x) + c_2 & \text{in } \{-1/\epsilon \le (x-p) \cdot \nu \le 0\}, \end{cases}$$

where  $c_1$  and  $c_2$  are constants satisfying  $l_1 = w_{\varepsilon} + c_1$  and  $l_2 = w_{\varepsilon} + c_2$  on  $\{(x - p) \cdot v = -1/\varepsilon\}$ . (See figure.)

Note that, due to (19), in  $\{-1/\varepsilon \le (x-p) \cdot \nu \le 0\}$  we have

$$\overline{w}(x) = \min(l_1(x), w_{\varepsilon}(x) + c_1)$$
 and  $\underline{w}(x) = \max(l_2(x), w_{\varepsilon}(x) + c_2),$ 

and thus it follows that  $\overline{w}$  and  $\underline{w}$  are respectively viscosity super- and subsolutions of (P).

#### 4. Let us define

$$h_1(x) = \eta^{\beta} \Big( (x - p) \cdot \nu + \frac{1}{\eta} \Big).$$

Then  $w^+ := \overline{w} + h_1$  solves

$$\begin{cases} F(Dw^+) \ge 0 & \text{in } \Omega_{\eta}, \\ \partial w^+ / \partial v = g(x) + \eta^{\beta} & \text{on } \Gamma_0, \end{cases}$$

and  $w^- := w - h_1$  solves

$$\begin{cases} F(Dw^{-}) \leq 0 & \text{in } \Omega_{\eta}, \\ \partial w^{-}/\partial v = g(x) - \eta^{\beta} & \text{on } \Gamma_{0}. \end{cases}$$

Since  $|g - \tilde{g}| \le \eta^{\beta}$  and  $w^+ = w^- = w_{\eta}$  on  $\{(x - p) \cdot v = -1/\eta\}$ , it follows from the comparison principle for  $(P_{\varepsilon})$  that

$$w^- \le w_\eta \le w^+ \quad \text{in } \Omega_\eta. \tag{20}$$

Hence we conclude

$$|\mu_{\eta} - \mu_{\varepsilon}| \le \Lambda(\varepsilon) + \eta^{\beta},\tag{21}$$

where 
$$\mu_{\eta}$$
 is the slope of  $v_{\eta}$ , and  $\Lambda(\varepsilon) = C\varepsilon^{\alpha/20} + Cw(\varepsilon)^{\beta} \to 0$  as  $\varepsilon \to 0$ .

The proof of the following lemma is immediate from Lemma 4.4 and (21).

**Lemma 4.5** (error estimate: Theorem 1.2(iv)). For any irrational direction v, there is a unique homogenized slope  $\mu(v) \in \mathbb{R}$  and  $\varepsilon_0 = \varepsilon_0(v) > 0$  such that for  $0 < \varepsilon < \varepsilon_0$ , the following holds: for any  $0 < \alpha < 1$ , there exists a constant  $C = C(\alpha, n, \lambda, \Lambda)$  such that

$$\left| u_{\varepsilon}(x) - \left( 1 + \mu(\nu)((x - p) \cdot \nu + 1) \right) \right| \le \Lambda(\varepsilon) := C \varepsilon^{\alpha/20} + C \omega_{\nu}(\varepsilon)^{\beta} \quad \text{in } \Pi_{\nu}(p), \tag{22}$$

where  $\omega_{\nu}(\varepsilon)$  is as given in (7).

**Lemma 4.6.** Let v be a rational direction. If the Neumann boundary  $\Gamma_0$  passes through p=0, then there is a unique homogenized slope  $\mu(v)$  for which the result of Lemma 4.5 holds with  $\Lambda(\varepsilon) = C\varepsilon^{\alpha/2}$ .

*Proof.* The proof is parallel to that of Lemma 4.4. Let  $w_{\varepsilon}$  and  $w_{\eta}$  be as given in the proof of Lemma 4.4. Note that since  $\Omega_{\varepsilon}$  and  $\Omega_{\eta}$  have their Neumann boundaries passing through the origin,  $\partial w_{\varepsilon}/\partial \nu = g(x) = \partial w_{\eta}/\partial \nu$  without translation of the x variable, and thus we do not need to use the properties of hyperplanes with an irrational normal (Lemma 2.7(b)) to estimate the error between the shifted Neumann boundary data.

**Remark 4.7.** As mentioned in the introduction, if  $\nu$  is a rational direction with  $p \neq 0$ , the values of  $g(\cdot/\varepsilon)$  on  $\partial\Omega_{\varepsilon}$  and  $\partial\Omega_{\eta}$  may be very different under any translation, and thus the proof of Lemma 4.4 fails. In this case,  $u_{\varepsilon}$  may converge to solutions of different Neumann boundary data, depending on the subsequence.

*Proof of Theorem 1.2*(ii). Recall that we must show that the homogenized limit  $\mu(v)$ , defined in Lemma 4.5 for irrational directions in  $\mathcal{G}^{n-1}$ , has a continuous extension  $\bar{\mu}(v): \mathcal{G}^{n-1} \to \mathbb{R}$ .

Fix a unit vector  $v \in \mathcal{G}^{n-1}$ . Then we will show that there exists a positive constant C > 0 depending on v such that the following holds: given  $\delta > 0$ , there exists  $\varepsilon > 0$  such that for any two irrational directions  $v_1, v_2 \in \mathcal{G}^{n-1}$ ,

$$|\mu(\nu_1) - \mu(\nu_2)| < C\delta^{1/2}$$
 whenever  $0 < |\nu_1 - \nu|, |\nu_2 - \nu| < \varepsilon.$  (23)

1. To simplify the proof, we first present the case n=2. For simplicity of notation, we may assume that  $|\nu \cdot e_1| \le |\nu \cdot e_2|$  and p=0. First we introduce several notations. Again for notational simplicity and clarity in the proof, we assume that  $\nu = e_2$ : we will explain in the paragraph below how to modify the notations and the proof for  $\nu \ne e_2$ . Let us define

$$\Omega_0 := \Pi_{\nu}(0) = \{(x, y) \in \mathbb{R}^2 : -1 \le y \le 0\},\$$

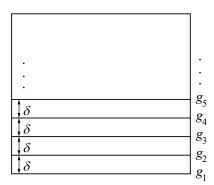

and for i = 1, 2,

$$\Omega_i := \Pi_{\nu_i}(0) = \{(x, y) \in \mathbb{R}^2 : -1 \le (x, y) \cdot \nu_i \le 0\}.$$

Let us also define the family of functions

$$g_i(x_1, x_2) = g_i(x_1) = g(x_1, \delta(i-1)),$$

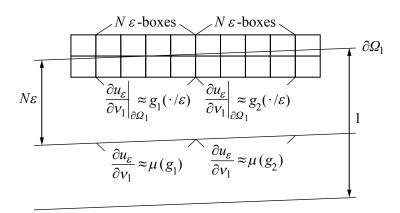

where  $i = 1, ..., m := [1/\delta] + 1$  (see figure).

If  $\nu$  is a rational direction different from  $e_2$ , take the smallest  $K_{\nu} \in \mathbb{N}$  such that  $K_{\nu}\nu = 0 \mod \mathbb{N}^2$ . Then g can be considered as a  $K_{\nu}$ -periodic function with the new direction of axis of  $\nu$ . If  $\nu$  is an irrational direction, take the smallest  $K_{\nu} \in \mathbb{N}$  such that  $|K_{\nu}\nu| \leq \delta \mod \mathbb{N}^2$ . Then g is almost  $K_{\nu}$ -periodic up to the order of  $\delta$  with the new axis of  $\nu$ . We point out that it does not make any difference in the proof if we replace the periodicity of g by the fact that g is almost periodic up to the order  $\delta$ .

Before moving on to the next step, we briefly discuss the heuristics in the proof.

*Proof by heuristics.* Since the domains  $\Omega_1$  and  $\Omega_2$  point toward different directions  $\nu_1$  and  $\nu_2$ , we cannot directly compare their boundary data, even if  $\partial \Omega_1$  and  $\partial \Omega_2$  cover most of the unit cell in  $\mathbb{R}^n/\mathbb{Z}^n$ . To overcome this difficulty, we perform a two-scale homogenization.

First we consider the functions  $g_i$   $(i=1,\ldots,m)$  whose profiles cover most values of g in  $\mathbb{R}^2$  up to the order of  $\delta^{\beta}$ , where  $\beta$  is the Hölder exponent of g. Note that most values of g in  $\mathbb{R}^2$  are taken on  $\partial \Omega_1$  and on  $\partial \Omega_2$ , since  $\nu_1$  and  $\nu_2$  are both irrational directions. On the other hand, since  $\nu_1$  and  $\nu_2$  are very close to  $\nu$ , which may be a rational direction, the averaging behavior of a solution  $u_{\varepsilon}$  in  $\Omega_1$  (or  $\Omega_2$ ) would occur only if  $\varepsilon$  gets very small.

If  $|\nu_1 - \nu| = |\nu_1 - e_2|$  is chosen much smaller than  $\delta$ , we can say that the Neumann data  $g_1(\cdot/\varepsilon)$  is (almost) repeated  $N := [\delta/|\nu_1 - \nu|]$  times on  $\partial \Omega_1$  with period  $\varepsilon$ , up to the error  $O(\delta^{\beta})$ . (See figure at the top of the page.) Similarly, on the next piece of the boundary,  $g_2(\cdot/\varepsilon)$  is (almost) repeated N times, and then  $g_3(\cdot/\varepsilon)$  is repeated N times: this pattern will repeat with  $g_k$  ( $k \in \mathbb{N} \mod m$ ).

If N is sufficiently large, that is, if  $|\nu_1 - \nu|$  is sufficiently small compared to  $\delta$ , the solution  $u_{\varepsilon}$  in  $\Omega_1$  will exhibit averaging behavior,  $N\varepsilon$ -away from  $\partial\Omega_1$ . More precisely, on the  $N\varepsilon$ -sized segments of hyperplane H located  $N\varepsilon$ -away from  $\partial\Omega_1$ ,  $u_{\varepsilon}$  would be homogenized by repeating the profiles of  $g_i$  (for some fixed i) with an error of  $O(\delta^{\beta})$ . This is the first homogenization of  $u_{\varepsilon}$  near the boundary of  $\Omega_1$ : we denote by  $\mu(g_i)$  the corresponding values of the homogenized slopes of  $u_{\varepsilon}$  on H.

Now a unit distance away from  $\partial\Omega_1$ , we obtain the second homogenization of  $u_{\varepsilon}$ , whose slope is determined by  $\mu(g_i)$ ,  $i=1,\ldots,m$ . Note that this estimate does not depend on the direction  $v_1$ , but on the quantity  $|v_1-v|$ . Hence, applying the same argument for  $v_2$ , we conclude that  $|\mu(v_1)-\mu(v_2)|$  is small. Note that  $\mu(v_1)$  and  $\mu(v_2)$  are uniquely determined because  $v_1$  and  $v_2$  are irrational directions (Lemma 4.6).

A rigorous proof of the above observation is rather lengthy: the main difficulty lies in the fact that to perform the first homogenization  $N\varepsilon$ -away from the boundary, one requires the solution  $u_{\varepsilon}$  to be sufficiently flat in tangential directions to  $\nu$ , which we do not know a priori. We will go around this difficulty by constructing sub- and supersolutions by patching up solutions from the near-boundary region and from the region away from the boundary. The proof is given in steps 2–8 below.

<sup>&</sup>lt;sup>1</sup>By (F3), we may assume that the arrangement of  $g_1, \ldots, g_m$  is the same for the directions  $v_1$  and  $v_2$ , after appropriate rotation and reflection (note that (F3) implies rotation and reflection invariance of the operator F).

2. Given  $\delta > 0$ , let us choose irrational unit vectors  $v_1, v_2 \in \mathbb{R}^2$  such that

$$0 < \bar{\varepsilon}_0^{1/1000} \le \varepsilon_0^{1/1000} \le \delta,$$

where  $\varepsilon_0 = |\nu_1 - e_2|$  and  $\bar{\varepsilon}_0 = |\nu_2 - e_2|$ . Let  $\varepsilon = \varepsilon_0^{21/20}$  and  $\bar{\varepsilon} = \bar{\varepsilon}_0^{21/20}$ . Let us also define

$$N = \left[\frac{\delta}{|\nu_1 - e_2|}\right] = \left[\frac{\delta}{\varepsilon_0}\right]. \tag{24}$$

Then  $N\varepsilon = \delta\varepsilon_0^{1/20} := \delta_0$ . Note that

$$\delta_0 \ge \varepsilon^{1/20}$$
 and  $\delta_0 \ge \delta^{100}$ .

With the above definition of  $\varepsilon$  and N, consider the strip regions  $I_0 = [-N\varepsilon, 0] \times \mathbb{R}$ ,  $I_1 = [0, N\varepsilon] \times \mathbb{R}$ ,  $I_{-1} = [-2N\varepsilon, -N\varepsilon] \times \mathbb{R}$ ,  $I_2 = [N\varepsilon, 2N\varepsilon] \times \mathbb{R}$ , ..., that is,

$$I_k = [(k-1)N\varepsilon, kN\varepsilon] \times \mathbb{R}$$
 for  $k \in \mathbb{Z}$ .

Let  $\tilde{k} \in [1, m]$  denote k in modulo m, where  $m = [1/\delta] + 1$ . Note that, since  $N|\nu_1 - e_2| = \delta$ ,  $g_{\tilde{k}}(\cdot/\varepsilon)$  is (almost) repeated N times on  $I_k \cap \partial \Omega_1$ . This fact and the Hölder continuity of g yield that

$$\left| g\left(\frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) - g_{\tilde{k}}\left(\frac{x}{\varepsilon}\right) \right| < C\delta^{\beta} \quad \text{on } \partial\Omega_1 \cap I_k, \quad \text{for } k \in \mathbb{Z}.$$
 (25)

3. Let  $w_{\varepsilon}$  solve  $(P): F(D^2w_{\varepsilon}) = 0$  in  $\Omega_0$ , with

$$\begin{cases} \frac{\partial w_{\varepsilon}}{\partial \nu}(x,0) = g_{\tilde{k}}\left(\frac{x}{\varepsilon}\right) & \text{for } (x,0) \in I_k, \\ w_{\varepsilon} = 1 & \text{on } \{y = -1\}. \end{cases}$$

Next let  $u_{\varepsilon}$  solve (P) in  $\Omega_1$ , with

$$\begin{cases} \frac{\partial u_{\varepsilon}}{\partial \nu_{1}}(x,0) = g\left(\frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) & \text{on } \{(x,y) \cdot \nu_{1} = 0\}, \\ u_{\varepsilon} = 1 & \text{on } \{(x,y) \cdot \nu_{1} = -1\}. \end{cases}$$

Let  $\mu(w_{\varepsilon})$  ( $\mu(u_{\varepsilon})$ ) be chosen as the slope  $\mu_j$  in the linearized problem ( $P_{\mu_j}$ ) in Section 4, where  $u_j$  is replaced by  $w_{\varepsilon}$  ( $u_{\varepsilon}$ ) and the reference point x=0 is replaced by  $x=-e_2/2=(0,-\frac{1}{2})$ . (Recall that we assumed  $0 \in \partial \Omega_1$ , and  $(0,-\frac{1}{2}) \in \Omega_i$  for i=1,2.) Then  $\mu(w_{\varepsilon})$  and  $\mu(u_{\varepsilon})$  denote the slopes of a linear approximation of  $w_{\varepsilon}$  and  $u_{\varepsilon}$ . From (25) it follows that

$$|\mu(w_{\varepsilon}) - \mu(u_{\varepsilon})| < C\delta^{\beta}. \tag{26}$$

We point out that  $\mu(w_{\varepsilon})$  and  $\mu(u_{\varepsilon})$  respectively converge to a unique limit as  $\varepsilon \to 0$ , since  $\nu_1$  is irrational.

4. We begin by introducing  $\mu_{1/N}(g_k)$ , which denotes the average slope of a solution with Neumann data  $g_k(x/\varepsilon)$ ,  $\delta_0$ -away from the Neumann boundary  $\{y=0\}$ . (Here note that  $\delta_0=N\varepsilon$ .)

Let us define

$$H := \partial \Omega_0 - N\varepsilon e_2 = \{(x, y) : y = -\delta_0\}.$$

Let  $\eta = 1/N$  and let  $w_{\eta,1}$  solve

$$\begin{cases} F(D^2w_{\eta,1}) = 0 & \text{in } \{-\delta_0 \le y \le 0\}, \\ w_{\eta,1} = w_{\varepsilon}(0, -\delta_0) & \text{on } H = \{y = -\delta_0\}, \\ \frac{\partial w_{\eta,1}}{\partial y}(x, 0) = g_1\left(\frac{x}{\varepsilon}, 0\right) & \text{on } \partial \Omega_0 = \{y = 0\}, \end{cases}$$

where  $g_1(x, 0) = g_1(x + k, 0)$  for  $k \in \mathbb{Z}$ . Let  $\mu_{1/N}(g_1)$  be the slope of the linear approximation of  $w_{\eta, 1}$ , defined as follows: choose a linear solution  $v_{\eta, 1}(\cdot)$  such that

$$\begin{cases} F(D^2 v_{\eta,1}) = 0 & \text{in } \{-\delta_0 \le y \le 0\}, \\ v_{\eta,1} = w_{\eta,1}(0, -\delta_0) & \text{on } H = \{y = -\delta_0\}, \\ v_{\eta,1}\Big(0, -\frac{\delta_0}{2}\Big) = w_{\eta,1}\Big(0, -\frac{\delta_0}{2}\Big), \\ \frac{\partial v_{\eta,1}}{\partial y}(x, 0) = \mu_{1/N}(g_1) & \text{on } \partial \Omega_0 = \{y = 0\}. \end{cases}$$

Since  $g_1(x/\varepsilon, 0)$  is periodic on  $\{y = 0\}$  with period  $\varepsilon$  and  $\delta_0 = N\varepsilon$ , we can apply Lemma 4.2(i), using the fact that  $\delta_0 \ge \varepsilon^{1/20}$ , to conclude that

$$\left| w_{\eta,1}(x,y) - \left( w_{\eta,1} \left( 0, -\frac{\delta_0}{2} \right) + \mu_{1/N}(g_1) \left( y + un \frac{\delta_0}{2} \right) \right) \right| \le C \delta_0^{1+\beta} \tag{27}$$

on  $\{y = -\delta_0/2\} \cap I_1$ . Similarly, one can define  $w_{\eta,k}$  and  $v_{\eta,k}$  for  $k \in \mathbb{Z}$  to conclude that

$$\left| w_{\eta,k}(x,y) - \left( w_{\eta,k} \left( (k-1)\delta_0, -\frac{\delta_0}{2} \right) + \mu_{1/N}(g_{\tilde{k}}) \left( y + \frac{\delta_0}{2} \right) \right) \right| \le C \delta_0^{1+\beta} \tag{28}$$

on  $\{y = -\delta_0/2\} \cap I_k$ .

5. We will now construct barriers which bound  $w_{\varepsilon}$  from above and below, by pasting together the near-boundary and the rest of the region together as follows. First we construct a supersolution of  $(P_{\varepsilon})$ . Let  $\rho_{\varepsilon}$  solve the Neumann boundary problem away from the boundary  $\{y=0\}$ :

$$\begin{cases} F(D^2 \rho_{\varepsilon}) = 0 & \text{in } \{-1 \le y \le -\delta_0\}, \\ \frac{\partial \rho_{\varepsilon}}{\partial y} = \Lambda(x) & \text{on } H = \{y = -\delta_0\}, \\ \rho_{\varepsilon} = 1 & \text{on } \{y = -1\}. \end{cases}$$

Here  $\Lambda(x)$  is a Hölder continuous function obtained by approximating  $\mu_{1/N}(g_k) + 2\delta_0^{\alpha_0}$  in each  $N\varepsilon$ -strip, where the constant  $0 < \alpha_0 < 1$  will be decided below. Here the Hölder continuity of  $\Lambda(x)$  is obtained by the fact that  $g_k$  and  $g_j$  differ from each other by  $((k-j)\delta)^{\beta}$  and they are apart by  $(k-j)N\varepsilon \ge (k-j)\delta^{100}$ .

Then Theorem 2.4(b) yields that  $\rho_{\varepsilon} \in C^{1,\gamma}$  up to H, where  $\gamma$  depends on  $\beta$  and n. Therefore there exists a constant  $0 < \alpha_0 < 1$  such that the following holds: in each  $\delta_0^{1-\alpha_0}$ -neighborhood of a point  $(x_0, -\delta_0) \in H$ , we have

$$\left| \rho_{\varepsilon}(x, -\delta_0) - \rho_{\varepsilon}(x_0, -\delta_0) - \alpha(x_0)(x - x_0) \right| \le \delta_0^{1 + \alpha_0},\tag{29}$$

where  $\alpha(x_0)$  is the tangential derivative of  $\rho_{\varepsilon}$  at  $(x_0, -\delta_0)$ .

6. Next we construct the near-boundary barrier:

$$\begin{cases} F(D^2 f_{\varepsilon}) = 0 & \text{in } \{-\delta_0 \le y \le 0\}, \\ f_{\varepsilon} = \rho_{\varepsilon} & \text{on } H = \{y = -\delta_0\}, \\ \frac{\partial f_{\varepsilon}}{\partial y} = g_{\tilde{k}} \left(\frac{x}{\varepsilon}\right) & \text{on } \{y = 0\} \cap I_k. \end{cases}$$

Let us now estimate the slope of  $f_{\varepsilon}$  on H. Let us choose a constant  $\mu_{\varepsilon}$  and the corresponding linear profile  $\phi_{\varepsilon}$  such that

 $\begin{cases} F(D^2\phi_{\varepsilon}) = 0 & \text{in } \{-\delta_0 \le y \le 0\}, \\ \phi_{\varepsilon}(x, -\delta) = f_{\varepsilon}(0, -\delta_0) & \text{on } H, \\ \phi_{\varepsilon}\left(0, -\frac{\delta}{2}\right) = f_{\varepsilon}\left(0, -\frac{\delta_0}{2}\right), \\ \frac{\partial \phi_{\varepsilon}}{\partial y} = \mu_{\varepsilon} & \text{on } \partial \Omega_0 = \{y = 0\}. \end{cases}$ 

Equation (29) and the comparison principle (Theorem 2.2), as well as the localization argument as in the proof of Lemma 3.1 applied to the rescaled function

$$(\delta_0)^{-1} f_{\varepsilon} \left( \frac{(x - x_0)}{\delta_0} + x_0, \frac{y}{\delta_0} \right) - \alpha(x_0)(x - x_0)$$

in the region  $\{-1 \le y \le 0\} \cap \{|x| \le \delta_0^{-\alpha_0}\}$ , yields that

$$|\phi_{\varepsilon} - f_{\varepsilon}| \le C\delta_0^{1+\alpha_0} \quad \text{in } \{-\delta_0 \le y \le 0\} \cap \{|x| \le \delta_0^{1-\alpha_0}\}. \tag{30}$$

Putting the estimates (28) and (30) together, it follows that for any  $(x_0, -\delta_0) \in H$ , we have

$$\left| f_{\varepsilon}(x,y) - \left( \alpha(x_0)(x - x_0) + \mu_{1/N}(g_k) \left( y + \frac{\delta_0}{2} \right) \right) \right| \le \delta_0^{1 + \alpha_0} \quad \text{on } \left\{ y = -\frac{\delta_0}{2} \right\} \cap \left\{ |x - x_0| \le \delta_0^{1 - \alpha_0} \right\},$$

for appropriate k in each  $\delta$ -strip. Using the above inequality, (29), and the  $C^{1,\gamma}$  regularity of  $f_{\varepsilon}$  up to its Dirichlet boundary, we obtain that

 $\frac{\partial f_{\varepsilon}}{\partial y} \leq \Lambda(x),$ 

which then makes the following function a supersolution of  $(P_{\varepsilon})$ :

$$\underline{\rho}_{\varepsilon} := \begin{cases} \rho_{\varepsilon} & \text{in } \{-1 \le y \le -\delta_0\}, \\ f_{\varepsilon} & \text{in } \{-\delta_0 \le y \le 0\}. \end{cases}$$

Similarly, one can construct a subsolution  $\bar{\rho}_{\varepsilon}$  of  $(P_{\varepsilon})$  by replacing  $\Lambda(x)$  given in the construction of  $\rho_{\varepsilon}$  by  $\tilde{\Lambda}(x) := \Lambda(x) - 4\delta_0^{\alpha_0}$ , such that

$$\bar{\rho}_{\varepsilon} \le w_{\varepsilon} \le \rho_{\varepsilon}.$$
 (31)

7. Parallel arguments as in steps 2–6 apply to the other direction,  $v_2$ : if we define  $\bar{\epsilon}_0$ , M and  $\bar{H}$  by

$$|\nu_2 - e_2| = \bar{\varepsilon}_0 < \varepsilon_0, \quad M = \left[\frac{\delta}{\bar{\varepsilon}_0}\right], \quad \bar{\varepsilon} = \bar{\varepsilon}_0^{21/20} \quad \text{and} \quad \bar{H} = \{y = -M\bar{\varepsilon}\},$$

then we can construct barriers  $\bar{\rho}_{\bar{\varepsilon}}$  and  $\underline{\rho}_{\bar{\varepsilon}}$  such that

$$\bar{\rho}_{\bar{\varepsilon}} \le w_{\bar{\varepsilon}}(x) \le \underline{\rho}_{\bar{\varepsilon}},\tag{32}$$

with their corresponding Neumann boundary conditions on H:

$$\frac{\partial}{\partial y}\bar{\rho}_{\bar{\varepsilon}}, \quad \frac{\partial}{\partial y}\underline{\rho}_{\bar{\varepsilon}} = \mu_{1/M}(g_{\bar{k}}) + O(\bar{\delta}_0^{\alpha_0}) \quad \text{and} \quad \bar{H} \cap I_k,$$
 (33)

where their respective derivative is taken as a limit from the region  $\{-1 \le y < -\bar{\delta}_0\}$ .

8. Now we proceed to estimate the averaging behavior of  $u^{\varepsilon}$  away from the Neumann boundary. By (21) of Lemmas 4.4 and 4.6,

$$\left|\mu_{1/N}(g_{\tilde{k}}) - \mu_{1/M}(g_{\tilde{k}})\right| < \Lambda\left(\frac{1}{N}\right) + \left(\frac{1}{M}\right)^{\beta},\tag{34}$$

where  $\Lambda\left(\frac{1}{N}\right) = CN^{-\alpha/2}$ . Let us write  $\mu_{1/N}(g_{\tilde{k}}) = \mu_{\tilde{k},N}$ , and let h and  $\bar{h}$  respectively solve

$$\begin{cases} F(D^2h) = 0 & \text{in } \{-1 \le y \le -N\varepsilon\}, \\ h = 1 & \text{on } \{y = -1\}, \\ \frac{\partial h}{\partial \nu} = \mu_{\tilde{k},N} & \text{on } H \cap I_k, \end{cases}$$

and

$$\begin{cases} F(D^2\bar{h}) = 0 & \text{in } \{-1 \le y \le -M\bar{\varepsilon}\}, \\ \bar{h} = 1 & \text{on } \{y = -1\}, \\ \frac{\partial \bar{h}}{\partial \nu} = \mu_{\tilde{k},M} & \text{on } \bar{H} \cap I_k. \end{cases}$$

Let  $\mu(h)$  and  $\mu(\bar{h})$  be the respective slope of linear approximation for h and  $\bar{h}$ .

Then it follows from (34) that if  $\delta_0 \sim N\varepsilon$  and  $\bar{\delta}_0 \sim M\bar{\varepsilon}$  are sufficiently small,

$$|\mu(h) - \mu(\bar{h})| < C\left(m\left(\frac{1}{N}\right) + \left(\frac{1}{M}\right)^{\beta}\right). \tag{35}$$

Lastly, observe that by (31) and (32), there exists  $0 < \gamma < 1$  such that

$$|\mu(w_{\varepsilon}) - \mu(h)| < C\delta^{\gamma}$$
 and  $|\mu(w_{\bar{\varepsilon}}) - \mu(\bar{h})| < C\delta^{\gamma}$ .

The above inequalities and (35) yield

$$|\mu(w_{\varepsilon}) - \mu(w_{\bar{\varepsilon}})| < C\left(\delta^{\gamma} + m\left(\frac{1}{N}\right) + \left(\frac{1}{M}\right)^{\beta}\right).$$

Then we conclude from (26) that

$$|\mu(u_{\varepsilon}) - \mu(u_{\bar{\varepsilon}})| < C\left(\delta^{\gamma} + m\left(\frac{1}{N}\right) + \left(\frac{1}{M}\right)^{\beta}\right). \tag{36}$$

9. Lastly, we estimate the rate of convergence of  $\mu(u_{\varepsilon})$  to  $\mu(v_1)$  as  $\varepsilon \to 0$ . The claim is that

$$|\mu(\nu_1) - \mu(u_{\varepsilon})| \le C \left(\varepsilon_0^{\beta} + \varepsilon_0^{21\alpha/200} + \varepsilon_0^{1/20}\right).$$

We will argue similarly as in the proof of Lemma 4.2(ii). Let us define  $v^{\varepsilon}$ , the linear approximation of  $u_{\varepsilon}$ , as in  $(P_{\mu_i})$  of page 960, where the reference function  $u_j$  is replaced by  $u_{\varepsilon}$ .

Recall that  $\Omega_1 = \{y : -1 \le y \cdot \nu_1 \le 0\}$ . We define

$$\tilde{\Omega}_1 := \Omega_1 \cap \{ y : y \cdot \nu_1 \le -N\varepsilon\delta^{-1}\nu_1 \}$$

and  $L := \partial \Omega_1 - N\varepsilon \delta^{-1} \nu_1$ . For any given  $x_0 \in L$  and for any  $x \in L$ , there exists  $y \in \mathbb{R}^2$  such that  $|x - y| \le N\varepsilon m$ ,  $x_0 - y = 0 \mod \varepsilon \mathbb{Z}^2$ , and

$$\operatorname{dist}(y, L) \leq \varepsilon |v_1 - e_2| = \varepsilon \varepsilon_0.$$

(Recall that  $m = \left\lceil \frac{1}{\delta} \right\rceil + 1$ .) Then by arguing as in (15), for  $x \in L$ ,

$$|u_{\varepsilon}(x_0) - u_{\varepsilon}(x)| \le C\varepsilon_0^{\beta} + C(N\varepsilon\delta^{-1})^{\alpha}(N\varepsilon m)^{\alpha} \le C(\varepsilon_0^{\beta} + \varepsilon^{\alpha/10}).$$

Hence, due to the comparison principle (Theorem 2.2) applied to  $u_{\varepsilon}$  and  $v_{\varepsilon}$  in the domain  $\tilde{\Omega}_1$ , we obtain

$$|u_{\varepsilon} - v_{\varepsilon}| \le C(\varepsilon_0^{\beta} + \varepsilon^{\alpha/10} + N\varepsilon\delta^{-1}) = C(\varepsilon_0^{\beta} + \varepsilon_0^{21\alpha/200} + \varepsilon_0^{1/20}). \tag{37}$$

Following the proof of (21) using (37) instead of (13), we conclude

$$|\mu(u_{\varepsilon}) - \mu(v_1)| \le C(\varepsilon_0^{\beta} + \varepsilon_0^{21\alpha/200} + \varepsilon_0^{1/20}) \le \delta.$$

Parallel arguments apply to  $\nu_2$ . Combining the above inequality with (36),

$$|\mu(\nu_1) - \mu(\nu_2)| \le C\left(\delta^{\gamma} + m\left(\frac{1}{N}\right) + \left(\frac{1}{M}\right)^{\beta}\right).$$

Since N and M grow to infinity as  $\varepsilon$  and  $\bar{\varepsilon}$  go to zero, the above inequality proves the lemma.

10. For the general dimensions n > 2, let us define

$$g_i(x_1, \ldots, x_{n-1}, x_n) = g_i(x_1, \ldots, x_{n-1}) = g(x_1, \ldots, x_{n-1}, \delta(i-1))$$

for  $i = 0, 1, ..., m := [\delta^{-1}]$ . Let us also define

$$I_{k_1,k_2,\ldots,k_{n-1}} := \left[ (k_1 - 1)N\varepsilon, k_1N\varepsilon \right] \times \cdots \times \left[ (k_{n-1} - 1)N\varepsilon, k_{n-1}N\varepsilon \right] \times \mathbb{R}.$$

Then parallel arguments as in steps 1–9 would apply to yield the proposition in  $\mathbb{R}^n$ .

**Remark 4.8.** The proof breaks down for  $F = F(D^2u, x/\varepsilon)$ , since the idea of perturbing the problem by tilting the Neumann boundary and its boundary data, that is, the approximation of  $u_{\eta}$  by  $w_{\eta}$  in step 3, does not apply if the inside operator also depends on  $x/\varepsilon$ .

#### Acknowledgements

We thank Takis Souganidis for helpful discussions as well as for motivating the problem. We also thank Luis Caffarelli for helpful discussions regarding Remark 1.3.

#### BOARD OF EDITORS

Michael Aizenman	Princeton University, USA aizenman@math.princeton.edu	Nicolas Burq	Université Paris-Sud 11, France nicolas.burq@math.u-psud.fr
Luis A. Caffarelli	University of Texas, USA caffarel@math.utexas.edu	Sun-Yung Alice Chang	Princeton University, USA chang@math.princeton.edu
Michael Christ	University of California, Berkeley, USA mchrist@math.berkeley.edu	Charles Fefferman	Princeton University, USA cf@math.princeton.edu
Ursula Hamenstaedt	Universität Bonn, Germany ursula@math.uni-bonn.de	Nigel Higson	Pennsylvania State Univesity, USA higson@math.psu.edu
Vaughan Jones	University of California, Berkeley, USA vfr@math.berkeley.edu	Herbert Koch	Universität Bonn, Germany koch@math.uni-bonn.de
Izabella Laba	University of British Columbia, Canada ilaba@math.ubc.ca	Gilles Lebeau	Université de Nice Sophia Antipolis, France lebeau@unice.fr
László Lempert	Purdue University, USA lempert@math.purdue.edu	Richard B. Melrose	Massachussets Institute of Technology, USA rbm@math.mit.edu
Frank Merle	Université de Cergy-Pontoise, France Frank.Merle@u-cergy.fr	William Minicozzi II	Johns Hopkins University, USA minicozz@math.jhu.edu
Werner Müller	Universität Bonn, Germany mueller@math.uni-bonn.de	Yuval Peres	University of California, Berkeley, USA peres@stat.berkeley.edu
Gilles Pisier	Texas A&M University, and Paris 6 pisier@math.tamu.edu	Tristan Rivière	ETH, Switzerland riviere@math.ethz.ch
Igor Rodnianski	Princeton University, USA irod@math.princeton.edu	Wilhelm Schlag	University of Chicago, USA schlag@math.uchicago.edu
Sylvia Serfaty	New York University, USA serfaty@cims.nyu.edu	Yum-Tong Siu	Harvard University, USA siu@math.harvard.edu
Terence Tao	University of California, Los Angeles, US tao@math.ucla.edu	SA Michael E. Taylor	Univ. of North Carolina, Chapel Hill, USA met@math.unc.edu
Gunther Uhlmann	University of Washington, USA gunther@math.washington.edu	András Vasy	Stanford University, USA andras@math.stanford.edu
Dan Virgil Voiculescu	University of California, Berkeley, USA dvv@math.berkeley.edu	Steven Zelditch	Northwestern University, USA zelditch@math.northwestern.edu

#### PRODUCTION

production@msp.org Silvio Levy, Scientific Editor

See inside back cover or msp.org/apde for submission instructions.

The subscription price for 2013 is US \$160/year for the electronic version, and \$310/year (+\$35, if shipping outside the US) for print and electronic. Subscriptions, requests for back issues from the last three years and changes of subscribers address should be sent to MSP.

Analysis & PDE (ISSN 1948-206X electronic, 2157-5045 printed) at Mathematical Sciences Publishers, 798 Evans Hall #3840, c/o University of California, Berkeley, CA 94720-3840, is published continuously online. Periodical rate postage paid at Berkeley, CA 94704, and additional mailing offices.

APDE peer review and production are managed by EditFLOW® from Mathematical Sciences Publishers.

# **ANALYSIS & PDE**

## Volume 6 No. 4 2013

Cauchy problem for ultrasound-modulated EIT GUILLAUME BAL	751
Sharp weighted bounds involving $A_{\infty}$ TUOMAS HYTÖNEN and CARLOS PÉREZ	777
Periodicity of the spectrum in dimension one ALEX IOSEVICH and MIHAL N. KOLOUNTZAKIS	819
A codimension-two stable manifold of near soliton equivariant wave maps  IOAN BEJENARU, JOACHIM KRIEGER and DANIEL TATARU	829
Discrete Fourier restriction associated with KdV equations YI HU and XIAOCHUN LI	859
Restriction and spectral multiplier theorems on asymptotically conic manifolds COLIN GUILLARMOU, ANDREW HASSELL and ADAM SIKORA	893
Homogenization of Neumann boundary data with fully nonlinear operator SUNHI CHOI, INWON C. KIM and KI-AHM LEE	951
Long-time asymptotics for two-dimensional exterior flows with small circulation at infinity THIERRY GALLAY and YASUNORI MAEKAWA	973
Second order stability for the Monge–Ampère equation and strong Sobolev convergence of optimal transport maps	993
GUIDO DE PHILIPPIS and ALESSIO FIGALLI
